PART I EXPLAINING CERTIFICATION

INTRODUCTION

Welcome to the interpretation guideline for the eighth issue of the Global Standard for Food Safety (hereafter referred to as the Standard). The interpretation guideline is designed to provide an accompaniment to Issue 8 of the Standard and should be read in conjunction with the Standard. The full details of the certification process and protocol are contained within the Standard.

This document helps in the understanding of each requirement of the Standard and identifies methods of compliance.

Examples are given to explain the type of documents, procedures and level of detail that would be required by a certification auditor.

The contents of the guideline are designed to help interpret the Standard across all food sectors; however, the exact requirements for any particular product, process or site will be specific to that industry and situation. Users of the guideline are therefore cautioned not to rely solely on the information provided here, but also to reconfirm needs on a product-by-product basis. Both legislative and voluntary safety requirements change frequently, highlighting the need for regular checks of precise requirements.

While adherence to the guideline does not specifically form part of the requirement to achieve certification to the Standard (i.e. they do not form part of the audit requirements), companies will need to demonstrate that they have taken account of the topics addressed within this guideline. Examples are given as points to consider but should always be used in the correct context relevant to the business. Practices should be able to withstand challenge by an auditor and be in line with good industry practices.

Achieving a particular requirement is based on evidence collected and observations made during the audit, and on the procedures expected within that industry sector. The level of non-conformity assigned by an auditor against a requirement of the Standard is an objective judgement with respect to severity and risk, and is based on the evidence seen during the audit and independently verified by the certification body management.

CERTIFICATION TO THE STANDARD

WHY IS CERTIFICATION REQUIRED?

Certification to the Standard was developed to establish a common standard for food safety and product quality management, allowing brand owners to demonstrate control and satisfy legal responsibility for products and consumer safety, as well as reducing audit duplication for manufacturers. The Standard has become a benchmark for best practice and is recognised worldwide by brand owners and manufacturers in the supply chain, with more than 20,000 food companies now certificated to the Standard. The Standard has been developed for manufacturers of food; however, certification throughout the supply chain is available through other BRC Global Standards:

- Global Standard for Packaging and Packaging Materials
- Global Standard for Storage and Distribution
- Global Standard for Consumer Products
- Global Standard for Agents and Brokers
- Global Standard for Retail.

FIRST STEPS TO GAINING CERTIFICATION

SELF-AUDIT OR GAP ANALYSIS

Once the decision has been made by the company to pursue certification to the Standard, the requirements need to be understood. The site needs to be assessed with regard to its current status, and areas that need to be improved must be identified. This may, for example, relate to the structure of buildings, equipment requirements, the design of processes or the documentation and implementation of procedures. The company needs to establish an action plan.

Relevant staff need to understand what is expected. Training courses or further information are available and may be useful.

A gap analysis or self-audit needs to be conducted. This could be undertaken in-house – for example, incorporated into the company's internal audit process. However, it may require external resources in the form of consultancy expertise, or a pre-assessment may be undertaken by the company's chosen certification body.

Once the company has reviewed the gaps between the requirements and its current practices, the company's senior management needs to establish a plan to ensure that work is undertaken to fulfil the requirements. This could include, for example, updating of policies and procedures, training of staff, capital expenditure for equipment and maintenance of the building.

WHO UNDERTAKES CERTIFICATION AUDITS?

BRC Global Standards does not undertake the audits itself. BRC Global Standards is the Standard owner, documenting the requirements on behalf of stakeholders and controlling the operation of the certification scheme. The Standard is written by a committee of international representatives, coordinated by BRC Global Standards, including retailers, food industry representatives and certification bodies. The Global Standards team then controls how audits are undertaken through the specification of the audit protocol and supporting rules and regulations for certification bodies undertaking the certification audits. Monitoring of certification bodies is undertaken through independent accreditation – for example, by the United Kingdom Accreditation Service (UKAS) or the American National Standards Institute (ANSI), operating to internationally recognised protocols – and by BRC Global Standards.

Therefore, a certification body approved by BRC Global Standards needs to be selected by the company. There is a worldwide choice of such bodies; a list can be found at **www.brcdirectory.com**. Certification bodies need to be appropriately qualified to undertake the audit and conform to the company's and its customers' requirements.

COST OF AUDITS

Audit costs vary and are set by the individual certification bodies. They may include the expenses of the auditor (e.g. travel).

Typically, the audit consists of 2 to 3 days on site, depending on factors such as company size (in terms of staff numbers and size of site), the complexity of the manufacturing process, communication difficulties (e.g. language) and difficulties during the audit.

A full list of factors is given in the Standard and an audit duration calculator is available. In addition, time is needed to write up the report – typically 0.5–1 day. As with most purchases, the cost should be clearly stated and agreed between the company and the certification body prior to entering into the contract.

It should be noted that certification is a continual process, and it is a feature of the scheme that the certification body has the option to visit a certificated company at any stage of certification to ensure that certification principles are being upheld. This may arise through the receipt of further information, such as a complaint from a customer of the site, and a charge may be made for any subsequent visits or investigations.

A service fee is payable directly to BRC Global Standards through the certification body for every audit undertaken.

The company also needs to consider investment costs that may be incurred to ensure the company is operating to the standards required by the Global Standard, including site standards, training and procedural costs.

WHEN CAN THE AUDIT BE UNDERTAKEN?

The company and the chosen certification body should agree a mutually convenient date for audits and re-audits to ensure that the company retains ongoing certification. (For certificated sites this may be yearly or 6-monthly, depending on the grade attained.) The company may wish to choose a date when:

- products that need to be included within the scope of the certificate are being manufactured
- personnel to be involved in the audit process are available.

Ongoing re-audit dates need to be considered since the re-audit date will fall between 11 and 12 months from the original audit date (or 5 to 6 months from the original audit date if a Grade C or D is obtained, where re-audit is required after 6 months). Ensure the time of year is suitable for your company in years to come.

WHAT TO EXPECT ON THE AUDIT DAY(S)

The auditor/certification body shall have confirmed to the company the time of arrival on site and may have provided an outline of the plan of the audit schedule. The duration of the audit, although planned in advance, will depend on the activities on the day, but it may be shortened by a well-organised site and information provided in advance as requested by the certification body.

The auditor will start with an opening meeting, which all the relevant company personnel (including the most senior production or operations manager on site) need to attend, to outline how the audit will be undertaken. This will enable agreement and organisation in terms of:

- staff who need to be available to discuss specific aspects
- documents that need to be provided
- rooms that need to be provided (e.g. consider where records are stored and how they can be supplied to the auditor)
- logistics to ensure that equipment, such as protective clothing, is provided.

The auditor is likely to require background details on the company and the process before any site tour, and may therefore look through a number of documents, including:

- company quality policies
- organisation structure
- Hazard Analysis and Critical Control Point (HACCP) documents.

Auditors will ask the company to carry out a traceability test while the auditor is on site, so it may be beneficial to start this process as soon as practical to allow collation of documents.

The auditor will need to see the manufacturing process in operation around the site, checking and challenging the operation of the company's procedures. The auditor will check policies, procedures and records for objective evidence that requirements are being met, and will ask for specific details and speak to a variety of staff. After the audit, the auditor will require some quiet time to write up evidence and collate details of non-conformities, in preparation for the closing meeting with the company, where the audit is summed up and details of the findings, including non-conformities, are given.

UNANNOUNCED AUDITS - IS THERE ANYTHING DIFFERENT?

The option to undertake the unannounced audit scheme provides companies with an opportunity to demonstrate their confidence in their systems and procedures, to the extent that they are willing to subject these to unannounced scrutiny.

Companies may thereby gain a competitive advantage with their customers, who are given an opportunity to review suppliers' risk ratings. Customers may view suppliers in the unannounced audit scheme more favourably, depending on performance, and they may reduce the frequency of their own customer audits as a result.

The unannounced audit scheme is voluntary and the decision to participate in the scheme rests with the certificated company. To opt into the scheme, companies must notify their certification body of their intention within the first 3 months following a qualifying audit; after this period only the announced scheme will be available.

The grading criteria will be as for the normal audit. Successful completion of the audit will result in the awarding of certification Grade AA+, A+, B+, C+ or D+, where the plus symbol indicates an unannounced audit, and this grade will appear on the certificate. This certificate will supersede the existing certificate.

While it may be accepted that the company would need to ensure that arrangements such as facilities to undertake meetings and review documentation are made available at short notice, an unannounced audit should not affect the logistics of how an audit is undertaken, and should be approached in the same way by both the auditor and the company. The company should consider the requirements for contingency plans in the event of documents, such as personnel records, being kept in locked cupboards and the nominated key holder being off-site (e.g. through the provision of spare keys).

Issue 8 of the Standard provides an unannounced audit option, where all aspects of the Standard are audited on an unannounced visit to the site. Full details of the unannounced audit scheme can be found in Part III, sections 3 and 4 of the Standard.

EXPLANATION OF TERMS

Within the Standard there are some specific terms and language used and a good starting point for interpreting the Standard is to be familiar with these terms and their context. A full glossary of these terms is given in Appendix 2.

STATEMENTS OF INTENT

Each main section or subsection of the requirements in the Standard begins with a statement of intent (SOI). This sets out the expected outcome of compliance with the requirements of that section. This forms part of the audit and all companies must comply with the statements of intent.

Below the statements of intent in the tables are more specific and detailed requirements (clauses) that, if applied appropriately, will help to achieve the stated objective of the requirement. All of the requirements and the statements of intent shall form part of the audit and must be complied with in order for a certificate to be issued.

FUNDAMENTAL REQUIREMENTS

The Standard contains certain requirements that have been designated as 'fundamental'. These are marked with the word 'FUNDAMENTAL' and denoted with the following symbol . These requirements relate to systems that are crucial to the establishment and operation of an effective food quality and safety operation. The requirements deemed fundamental are:

- Senior management commitment and continual improvement (1.1)
- The food safety plan HACCP (2)
- Internal audits (3.4)
- Management of suppliers of raw materials and packaging (3.5.1)
- Corrective and preventive actions (3.7)
- Traceability (3.9)
- Layout, product flow and segregation (4.3)
- Housekeeping and hygiene (4.11)
- Management of allergens (5.3)
- Control of operations (6.1)
- Labelling and pack control (6.2)
- Training: raw material handling, preparation, processing, packing and storage areas (7.1).

Fundamental requirements apply to those controls that cannot be implemented quickly prior to an audit (e.g. management commitment, internal audits) and where the output of their implementation can be assessed. They are designed to ensure that the quality system will be effective between certification dates.

A lack of focus on a fundamental requirement may result in certification not being granted.

'SHALL' VERSUS 'MAY'

The style of the Standard is generally one of guidance, to allow companies to ensure that all aspects of control have been considered, so that thorough and comprehensive policies and procedures may be developed. In some instances the Standard requires that criteria must be included within a policy or procedure, and this is generally covered by the term 'shall'. If any of the points included are not covered adequately, a non-conformity will result.

However, there are also a number of clauses that provide examples or guidelines, generally preceded by the words 'may include' or 'should'. This information is provided as guidance for incorporation in company policies and procedures. It is the responsibility of the company to ensure that the auditor is satisfied that the system in place is appropriate.

Clause 3.11.1 shows an example of both usages:

'The company shall have documented procedures designed to report and effectively manage incidents and potential emergency situations that impact food safety, legality or quality. This shall include consideration of contingency plans to maintain product safety, quality and legality. Incidents may include ...'

HACCP, FOOD SAFETY PLAN, PREREQUISITES AND CRITICAL CONTROL POINTS

Specific terms (such as prerequisites or critical control points) are drawn from global terminology to describe expectations. Sites are not required to adopt the specific terminology used in the Standard (e.g. terms such as 'HACCP plan' and 'food safety plan' are equally acceptable). Alternative terminology may therefore be used, providing it is evident that all the requirements have been fully met. In the US, legislative requirements (detailed in the Food Safety Modernization Act) use different terminology but still incorporate all the requirements of the Standard.

RISK ASSESSMENT

A number of clauses within the Standard refer to risk assessments being the basis for developing appropriate control procedures, such as establishing a frequency for monitoring a control point. Risk assessment is defined as using judgement to identify hazards and determine their impact on food safety, legality or quality, and designing an appropriate control or procedure to minimise the risk of problems occurring.

During the course of the certification audit, the auditor will require evidence of these risk assessments. For example, these may take the form of documents that identify the hazard, the risk of it occurring and the options for control; alternatively, this information may be incorporated within established procedures.

Risk assessment is typically defined as a systematic process of evaluating the potential risks that may be involved in a projected activity or undertaking. For the purposes of the Standard, the scope of any risk assessment is limited to food safety, quality and legality, so an effective risk assessment will consider anything that might affect the product detrimentally. Risk assessments do not need to be long, complicated documents; they must, however, demonstrate which aspects have been assessed and, where further action has not been identified, some description of the justification will be required.

Sites are free to use electronic or physical tools to complete their risk assessments. Throughout the Standard, there is reference to the ability to use both, and sites should consider the purpose of the document, who will need to access it, and at what point in the process this access is needed (e.g. at the production line). Sites will also need to consider their methods of retention and document control procedures. The underlying principle is to demonstrate that any potential hazard has been considered, that the controls applied are justified, and that they will stand up to robust challenge by any auditor. In many cases, industry best practice, where known and available, will meet this requirement.

A risk assessment course is available from the BRC Academy and through the global network of approved training providers (ATPs). Take a look at the BRC Global Standards training pages for more details at **www.brcglobalstandards.com/training/**.

APPROPRIATE

A number of clauses within the Standard refer to the need to fulfil requirements 'where appropriate'. 'Appropriate' is defined as suitable for a particular condition or occasion, and requirements shall be met where it is an industry requirement or justified to do so.

A number of the requirements specify appropriate timescales, appropriate personnel etc., and thus contain a level of judgement.

They are designed to provide a degree of flexibility to ensure the operation of policies or procedures that are right for the organisation.

DOCUMENTED PROCEDURES

In many instances, the Standard specifically states that requirements shall be satisfied by documented procedures; in others, this is implied as the company needs to demonstrate that systems are in place. Any policies and documents must be written in sufficient detail to satisfy their purpose and must reflect the activities that happen in practice.

VALIDATION

Validation is defined as obtaining evidence that a control measure (or combination of measures), if properly implemented, is capable of controlling a hazard to a specified outcome. Validation activity is completed before the controls are introduced or when changes are expected (e.g., new products, new processes or new equipment). Validation might include:

- document and data review previous test results, industry data, codes of practice and legislation may all contain useful information
- experiments/testing consider tests on the product or factory environment that will demonstrate control (worst-case-scenario tests, final product tests etc.)
- challenge studies for example, microbiological tests to establish whether a micro-organism of concern can grow in the product using the relevant time/conditions
- modelling a number of predictive tools are available.

Several worked examples of validation can be found in Codex guideline CAC/GL 69-2008, available at **www.codexalimentarius.org/standards/list-of-standards**

VERIFICATION

Verification is defined as obtaining evidence, on a predetermined and ongoing basis, that a control is operating within the correct parameters. Verification requires the application of methods, procedures, tests or evaluations, in addition to monitoring, to determine whether the control measure is operating as intended. Verification activities may include:

- audits both internal and third party
- review of records (e.g. records of the monitoring of temperatures and times, or other records completed during production)
- corrective action review
- test results depending on the control being verified, these might include final products, raw materials, swabs, rapid tests etc.

MONITORING

Monitoring is defined as conducting a planned sequence of observations or measurements to assess whether a control measure is within acceptable limits (e.g. temperature checks, metal detector checks, test weights etc.).

ANNUAL FREQUENCY

Many requirements in the Standard refer to an annual frequency for the completion of, for example, internal audits or specific tasks. The aim of this specification is to ensure that certain tasks are completed within the minimum of a 12-month period (e.g. that the test of the system is completed every 12 months). There is a difference of 23 months between a test being carried out each January, and a test occurring in January one year, and December in the subsequent year.

PART II GUIDANCE ON THE REQUIREMENTS

1 SENIOR MANAGEMENT COMMITMENT

1.1 SENIOR MANAGEMENT COMMITMENT AND CONTINUAL IMPROVEMENT

FUNDAMENTAL

The site's senior management shall demonstrate they are fully committed to the implementation of the requirements of the Global Standard for Food Safety and to processes which facilitate continual improvement of food safety and quality management.

Interpretation

A fundamental factor in the management of product safety is the safety culture which prevails at the site; that is, the shared attitudes, values and beliefs relating to the importance of product safety, the confidence in the product safety processes used at the site, and the systems available to report and act on any concerns relating to product safety.

For this culture to flourish and for the importance of product safety to be understood by all members of staff, product safety needs to be led from the top of the organisation. This will ensure that the necessary commitment, support and resources are available.

Without this culture and management commitment, it is very unlikely that the Standard could be consistently applied or that the customer assurance provided by certification could be honoured. There are requirements within the Standard that need to be understood and applied by most functions within the organisation, from purchasing to personnel and from maintenance to production. Experience has shown that only where the most senior management are committed to the processes can this level of involvement be achieved consistently. Leadership behaviours, tendencies and management practices all influence the culture of safety, increasing the likelihood of the site adhering to good practice.

Senior managers should therefore be fully engaged in the implementation of and ongoing compliance with the Standard.

CLAUSE	REQUIREMENTS
The site shall have a documented policy which states the site's intention to meet its obligation to produce safe, legal and authentic products to the specified quality, and its responsibility to its contribution. This shall be:	
	signed by the person with overall responsibility for the sitecommunicated to all staff.
Interpretation	Documented policy The site's policy should clearly state the overall aims to meet customer requirements, including the provision of safe, authentic products of the quality desired by the customer. The policy is designed to show the site's intention, so that all staff can work towards this common goal.
	Authenticity of products means ensuring that all products sold or purchased are of the nature, substance and quality expected. This applies not just to product claims, but includes all products and raw materials with the assurance that they meet the specification. Authenticity is defined in the glossary (Appendix 2).
	The policy must be signed by the person with overall responsibility for the audited site, to demonstrate the commitment at senior management and site level. Where the policy is a group- or company-wide statement, the site management should endorse it; for example, by countersigning it.

CLAUSE

REQUIREMENTS

The policy statement is only a summary and can usually be expressed in a single page. Although it does not need to be dated, it must be current and should therefore be updated when significant policies or senior management change. The policy forms the foundation for the site's ways of working and the auditor will expect to see how the site management ensure staff understanding and engagement. This may include:

- communication to staff (e.g. through display on noticeboards, inclusion in the induction process, availability on the company intranet, and the use of appropriate languages where the local language is not the first language of all employees. The use of dual languages improves and speeds up understanding and action
- inclusion of all staff, including temporary and contract staff, in the communication and engagement processes.

1.1.2

The site's senior management shall define and maintain a clear plan for the development and continuing improvement of a food safety and quality culture. This shall include:

- defined activities involving all sections of the site that have an impact on product safety
- an action plan indicating how the activities will be undertaken and measured, and the intended timescales
- a review of the effectiveness of completed activities.

Interpretation

Food safety culture

A proactive, positive culture within a company can make all the difference in the effectiveness of the food safety and quality plan and its consistent implementation throughout the site. Culture must be led by senior management and 'felt' throughout the organisation, so that all aspects of the business are informed and involved.

Culture can be challenging. It relies not just on measurables and specifics but an ethos and values felt by people at all levels of the site. The size and complexity (or simplicity) of the site should not be a barrier to a successful culture. Good culture is also expressed through the ease of movement of information between different levels of the company.

The site is required to develop and implement a clear plan or programme for developing and improving its food safety culture. Such a plan would be based on the nature of the organisation, and dependent on its size, seasonality and the overall aims it has identified as important for its own culture.

The plan does not need to be annual. A strategic plan could, for example, cover 5 years, with activities designed to measure current culture, implement changes and assess improvements (or where improvement was not evident, a review of why). Some aspects of the plan may occur more frequently than others and the tools, metrics and measures for monitoring the plan should be demonstrable.

A wide range of activities could be incorporated into a culture development plan, some of which the company may already be conducting. For example:

- a staff survey focusing on values and culture
- annual staff reviews (one-to-ones) and recognition programmes
- feedback mechanisms (e.g. staff concerns)
- training review and staff development
- teamwork (e.g. staff involvement in setting product safety objectives)
- effective communication strategies
- activities to demonstrably maintain product safety standards.

The auditor will expect to find evidence of a plan with objectives, and evidence of the site completing the activities in its action plan. This will be determined through interviews and by viewing objective evidence of the steps taken.

Interviews may be conducted across all levels of personnel on an informal basis. They will be expected to find an awareness of food safety culture, how individuals can impact on it, and the company's objectives.

BRC Global Standards operates a module in product safety culture excellence which sites can elect to add to their BRC Global Standards audit. It will publish a guideline on product safety culture which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

CLAUSE REQUIREMENTS

Objectives or targets around food safety culture can be managed separately from, or together with, targets concerned with product safety, legality and quality. How they are managed depends on the nature of the food safety culture objectives and how they link with the site's other objectives.

Example Food safety culture strategic plan

A large company is creating a food safety culture plan. Senior management have recognised that employee attrition is a continual concern; each year they replace up to 35% of the total production staff. This means that productivity and on-time delivery are reduced because of the required upskilling of the new employees, and the site receives regular complaints from its customers of late deliveries and of non-conforming product.

The site's plan starts out quite simply by stating its intention to increase staff retention. Senior management start by surveying their employees anonymously to try to understand employee concerns. The site also starts to implement exit interviews for employees already leaving the company, and selected volunteers take part in one-to-one interviews with an external consultant.

Following these surveys, the site identifies that employees do not feel integral to the business, have difficulty in understanding how their actions impact on the company, and do not feel recognised by the management team.

The company decides to implement plans, including enhancement of training, communications, rewards and recognition. This includes:

- enhanced training beyond just managing critical control points (CCPs), to an understanding of the reasons for the current product safety processes and involvement in corrective actions
- communications regular staff updates in addition to the traditional internal message boards. Updates
 are used to communicate production, incidences of non-conforming product, customer complaints and
 their corrective actions, and improvements in product quality. They also focus on company strategy and
 product safety objectives
- a clear feedback process to initiate communication 'up' to management, so that communication is not just seen as management 'telling staff'
- recognition management instigate 'employee of the month' awards as rewards for successful process improvement ideas.

1.1.3

The site's senior management shall ensure that clear objectives are defined to maintain and improve the safety, legality and quality of products manufactured, in accordance with the food safety and quality policy and this Standard. These objectives shall be:

- documented and include targets or clear measures of success
- clearly communicated to relevant staff
- monitored and results reported at least quarterly to site senior management.

Interpretation

Food safety and quality objectives

Senior management must set objectives concerning food safety and quality which help to achieve the stated policy (see clause 1.1.1). The objectives must be communicated so that the relevant staff (i.e. those whose roles can affect product safety or quality) understand what is required from them. The setting of these objectives also helps the allocation of suitable budgets and resources. Auditors will look for evidence that the objectives are in place and have been communicated to staff.

Good objectives are usually:

- specific clear and directly related to the site's aims or goals for product safety and quality
- measurable so that the site can assess progress
- achievable targets that stretch the company are acceptable but it is important that they are realistic and that sufficient resources will be available
- relevant designed to maintain and improve product safety and quality
- time-bound either long term (e.g. throughout the period of certification) or shorter term (e.g. within the next 3 months); however, the timescales or deadlines should be clear to enable the site to review progress and, if necessary, amend activities.

CLAUSE

REQUIREMENTS

There are many examples of objectives that could be included. For example, reductions in:

- customer complaints
- non-conforming products
- audit failures or audit non-conformities include both internal and external audits
- customer rejections or returns.

In each of these examples it would be necessary for the site to consider how to make the objective specific and measurable (as discussed above); for example, 10% fewer customer complaints to be achieved by year end.

Progress against targets must be reviewed and reported to senior management at least quarterly. It may, for example, be included in management meetings (e.g. those scheduled for clause 1.1.4), or it may be the subject of a separate review or included in a report to the management. Auditors will look for documented evidence of the quarterly progress review.

Independent sites or facilities that are part of a large group with company-wide objectives can adopt the company-wide objectives, but are required to 'own' the objectives and carry out the implementation, monitoring, review etc. at site level.

1.1.4

Management review meetings attended by the site's senior management shall be undertaken at appropriate planned intervals, annually at a minimum, to review the site performance against the Standard and objectives set in clause 1.1.3. The review process shall include the evaluation of:

- previous management review action plans and timeframes
- the results of internal, second-party and/or third-party audits
- any objectives that have not been met, to understand the underlying reasons. This information shall be used when setting future objectives and to facilitate continual improvement
- any customer complaints and the results of any customer feedback
- any incidents (including both recalls and withdrawals), corrective actions, out-of-specification results and non-conforming materials
- the effectiveness of the systems for HACCP, food defence and authenticity
- resource requirements.

Records of the meeting shall be documented and used to revise the objectives. The decisions and actions agreed within the review process shall be effectively communicated to appropriate staff, and actions implemented within agreed timescales.

Interpretation

Senior management review

The purpose of the management review meeting is to take an overview of the food safety systems. The meeting should consider:

- what has been achieved
- progress against objectives
- identification of targets and areas of improvement for the coming year.

Senior management are considered to be managers who have the authority to make decisions on food safety objectives and/or the provision of adequate human and financial resources. The management team would usually include the site manager and those managers responsible for production, technical operations, purchasing, engineering and human resources. For large, multi-site organisations the management review meeting may include head office representatives, but this decision should be driven by the senior management on site.

The auditor will be looking for evidence that, for each agenda item, sufficient information has been provided to allow an informed discussion to take place leading to appropriate action plans. This may be demonstrated through a review of the inputs to the meeting, minutes of the discussion of the items and, where necessary, agreed action plans.

CLAUSE REQUIREMENTS

For example:

- To demonstrate that the senior management have reviewed the management of the Hazard Analysis and Critical Control Point (HACCP) system, the minutes should contain a general summary of the HACCP review meeting (see section 2.14) and a record of the outcomes of the HACCP meeting (these would be inputs into the management review meeting), together with any actions requested during the senior management meeting (outputs of management review meeting).
- The food safety system and Standard requirements should have been reviewed as part of the internal audit programme throughout the preceding year. Individual issues should have been identified and acted upon at the time and, where necessary, escalated to the management team.
- Second or third parties may include customer audits, regulatory authority visits etc.

An agenda item on internal audits may be a summary of each internal audit in terms of the number of non-conformities, outstanding issues, a report on the key trends identified and underlying root cause(s), and suggestions for improvement. This stimulates a discussion and, where necessary, enables an action plan to be set for the next year (e.g. a change in the frequency of auditing particular areas, training needs or the introduction of new targets).

The Standard identifies specific agenda items that shall be included within the meeting; however, additional relevant subjects can also be included.

One of the outputs from the meeting is a review of performance against the objectives (clause 1.1.3) and the establishment of new or amended targets and objectives for the following year. This should be clearly documented within the minutes of the meeting.

A review is required where the site has not met its objectives. This review need not be exhaustive (such as a full root cause analysis) but the site should be able to understand why objectives were not met. The outcome would not be preventive action but continual improvement allowing the site to refine its future targets.

The outcomes from the review meeting must be communicated to the relevant staff to ensure implementation. It should be evident to the auditor how this has been achieved (e.g. cascaded through staff briefings or posted on noticeboards).

The Standard requires an annual review, such as a regular annual management review. Many companies opt to make a review or partial review more frequently (e.g. every 6 months or each quarter), either addressing all the points in summary (after other review meetings) or addressing one or two points in depth in each meeting. The number of meetings and the individual agendas should be based on company need, providing all relevant topics are covered within the 12-month period. Where timescales are attributed to actions, it should be evident that the actions are followed up and completed within the set timescale.

Further guidance

Developing effective management review meetings

Attendees

In addition to the senior management team, the meeting may also include representatives of any departments responsible for specific activities or actions to be discussed at the meeting.

Agenda

The Standard identifies specific agenda items that need to be included in the meeting:

- minutes of the previous meeting to ensure all actions have progressed to the appropriate timescales
- audit results (including internal, second-party and third-party audits) so non-conformities can be discussed and actions agreed
- customer complaints and customer performance reviews to ensure that these have been correctly actioned, and to assess any trends
- incidents, corrective actions, out-of-specification results and non-conforming materials, to assess the action taken and where necessary agree any follow-up activity
- review of the management of the HACCP

CLAUSE

REQUIREMENTS

- discussion of the management of existing or emerging issues relating to food defence and the authenticity of raw materials
- resource requirements
- review of the performance against current objectives and the setting of new targets; i.e. all the objectives set out in clause 1.1.3 should be reviewed and objectives for the forthcoming year agreed. It is particularly relevant to consider why an objective has not been met, as this can be very informative and allows future objectives (or other actions such as the product safety culture plan) to focus on areas where relevant, achievable actions can take place
- additional relevant subjects (when required).

It is important that sufficient information is presented to the meeting to enable a full discussion and, where appropriate, actions to be agreed.

Frequency of the meetings

At a minimum your meetings should be once a year, i.e. annual. You need to set the frequency and timing of the meeting to maximise input and ensure that actions are timely. For example, seasonal and temporary sites will need to ensure the meetings occur at an appropriate point in the season and that actions, targets or objectives can be completed within meaningful timescales. Some sites, therefore, may find it necessary to have two more management meetings: for example, one at the start of the season to set objectives, and one at the end of the season, when the season's information can be assessed. Alternatively, a management meeting shortly after an external audit allows any non-conformities to be included in the discussion and relevant corrective actions to be agreed.

All sites should have a predefined schedule so all participants are aware, in advance, of when the meetings will take place.

Documenting the meeting

Your auditor will be checking that the review meeting papers have been produced and circulated, that there are minutes of the discussion, and that there are agreed action plans. For example, one of the outputs from the meeting is a review of performance against the defined objectives and the establishment of new or amended targets and objectives for the following year. This should be documented within the minutes of the meeting.

The outcomes from the review meeting must be communicated to the relevant staff to ensure implementation. It should be evident to the auditor how this has been achieved; for instance, cascaded through staff briefings or posted on noticeboards.

Completing actions

Timescales should be attributed to all actions. It should be evident that actions are followed up and completed. For example, evidence of completion could be added to meeting records, or assessment of actions could be added to the internal audit programme.

Quick tips

- Ensure that the meeting is in everyone's diary.
- Make sure that sufficient information is presented at the meeting to allow a meaningful discussion.
- Ensure that actions from each meeting are completed in a timely manner.
- Ensure that management meetings are incorporated in the internal audit programme.

1.1.5

The site shall have a demonstrable meeting programme which enables food safety, legality, integrity and quality issues to be brought to the attention of senior management. These meetings shall occur at least monthly.

Employees shall be aware of the need to report any evidence of unsafe or out-of-specification product or raw materials, to a designated manager to enable the resolution of issues requiring immediate action.

CLAUSE **REQUIREMENTS** Interpretation Management meetings The objective of this clause is to ensure that there is a mechanism for food safety and quality issues to be raised and discussed at a senior management level within the site. Most sites have weekly or monthly management meetings and the inclusion of safety, legality and quality as an agenda item within this meeting is one way to meet the requirements of this clause. The auditor will require evidence of the discussion on the relevant food safety issues, such as the minutes of the meetings. A schedule for the meetings needs to be in place. Where a food safety hazard is identified by a staff member, the reporting function and subsequent activity should be sufficiently rapid to mitigate any food safety risks. A transfer of information from an employee to senior management regarding unsafe or out-of-specification product or raw materials is an example of good food safety culture. If employees feel supported and empowered to identify and report issues and make positive changes, this will typically reflect how they feel about the organisation and the ongoing food safety culture. The company shall have a confidential reporting system to enable staff to report concerns relating to 1.1.6 product safety, integrity, quality and legality. The mechanism (e.g., the relevant telephone number) for reporting concerns must be clearly communicated to staff. The company's senior management shall have a process for assessing any concerns raised. Records of the assessment and, where appropriate, actions taken, shall be documented. Interpretation Confidential reporting system (whistleblowing) From time to time, it may be necessary for individuals to report on hazards or infractions anonymously and confidentially (e.g. if a staff member felt that a genuine concern raised through other mechanisms, such as those covered in clause 1.1.5, had not been adequately addressed), so the site (or company) should have a system in place to manage this. Although the aim of the Standard is to ensure these reporting systems relate to product safety, integrity, quality and legality, the company may choose to incorporate all staff concerns into the system, and not limit it to concerns related to the scope of the Standard. The system used must ensure that the confidentiality of the employee reporting the concern is maintained (i.e. the employee's identity is not released to the site or company management) to protect any staff using it, and the confidential and anonymous nature of the system should be clear to all staff. Many food processors will also have whistleblowing systems established by the brand owners and retailers for which it produces. Where this is the case, the site is still required to have its own system as affected products may not relate to the specific brand owner. As well as gathering information, the site is required to collate and act on it. The auditor will expect to see a system in place, and transparency about the content of any reports and actions, although not the source of the original concern. Where possible, sites might consider an independent system that receives and processes any concerns raised with appropriate promptness. Where quality, safety or conformity of the product is at risk, for example, action should be immediate. This might be by using an independent consultant or a professional organisation that can act as an intermediary. Where local legal requirements prohibit certain activities around confidentiality or such reports, this will be

Additionally, BRC Global Standards operates the independent 'Tell BRC' facility. This is available via the BRC Global Standards website or it can be reached via email.

In some areas, local relevant regulatory authorities will have facilities for confidential reports about a site but

acknowledged by the auditor and compliance with this clause noted within the context of the legal

this does not mitigate the need for a site (or company) to have a system.

framework.

CLAUSE REQUIREMENTS Example The auditor sees a 'whistleblowing' policy which states that concerns can be reported using an online web form or telephone number, the content of which is collated and submitted to the production manager, technical manager and external consultant. This system facilitates the anonymisation of the source of the information but ensures that the information is submitted to many individuals who are able to act on the information. The company's senior management shall provide the human and financial resources required to produce food safely and in compliance with the requirements of this Standard. Interpretation Resources Sites must have sufficient financial and human resources to be able to maintain the food safety systems and

Sites must have sufficient financial and human resources to be able to maintain the food safety systems and produce safe food in order to achieve certification.

Although a review of resources forms part of the management review process (clause 1.1.3), it should not be restricted to a single annual discussion if there is a need to make changes to resource allocation during the course of the year.

As well as looking at the minutes of the management review meeting, auditors will also look at the type, number and root cause of non-conformities identified at the audit, as the ability of the site to meet the requirements of the Standard will partly demonstrate that the appropriate resources and skills are available.

Where external consultants have been used as the main source of technical knowledge, it is essential that the site can demonstrate that the consultant is readily available and that there is no compromise of product safety and legality. It must be ensured that day-to-day responsibilities are under the control of the site.

The auditor will examine this requirement during the site tour and desktop audit. The auditor will expect the site to demonstrate that it is adequately resourcing its product safety activities, which may include capital expenditure (e.g. for repairs or new equipment), staff levels and staff training.

1.1.8

The company's senior management shall have a system in place to ensure that the site is kept informed of and reviews:

- scientific and technical developments
- industry codes of practice
- new risks to authenticity of raw materials
- all relevant legislation in the country where the product will be sold (where known).

Interpretation

Technical knowledge and information

Food safety issues and legislative requirements are constantly changing. The objective of this clause is to ensure that sites remain up to date, are able to meet legislation and can adapt their food safety systems to protect against new threats. The company must be able to demonstrate that it maintains up-to-date knowledge of relevant legislation, scientific and technical developments, potential risks to raw materials (e.g. to the authenticity of the raw material) and industry codes of practice, such as Codex Alimentarius. Activities to achieve this may include:

- membership of a trade association that provides this service
- subscription to a service provider supplying legal updates
- help from government officials or local enforcement offices
- regular review of identified websites covering legislation and standards.

In addition to information relating to food safety, the site must also have a system to obtain and review information relating to the authenticity of raw materials and the potential for substitution or dilution of the ingredients. This information will be required to demonstrate compliance with clause 5.4.1.

The company needs to demonstrate that it can readily access, either directly or through a third party, legislation relating to the product in the country, state or territory where:

- the product is manufactured
- the product is sold to the ultimate consumer (if known).

The auditor will therefore look for evidence of systematic checking and of the process for ensuring the information is transferred into action as necessary.

Sites must understand and comply both with relevant food safety and labelling legislation in the country of manufacture and with any applicable legislation where the product can reasonably be expected to be sold.

CLAUSE	REQUIREMENTS
1.1.9	The site shall have a genuine, original hard copy or electronic version of the current Standard available and be aware of any changes to the Standard or protocol that are published on the BRC Global Standards website.
Interpretation	Availability of a copy of the Standard The aim of this clause is to ensure the site has easy access to all the relevant requirements for compliance and certification to the Standard. The site must therefore have an official copy of the Standard available in either paper or electronic form. Either a free or paid PDF copy of the Standard demonstrates compliance with this requirement. A subscription to BRC Participate provides an online version of the Standard (and interpretation and other guidelines) and therefore also meets this requirement.
	In addition, during the lifetime of the Standard, the BRC technical advisory committee (TAC) may be asked to:
	 review the wording of a requirement in the Standard or audit protocol provide an interpretation for a requirement rule on the grading of a non-conformity against a clause.
	Published TAC opinions are defined as 'position statements'. Position statements are binding on the way that the audit and certification process is carried out and are considered to be an extension to the Standard. Sites must therefore be aware of any published position statements and, where necessary, ensure the information is transferred into action. Position statements are published on the BRC Global Standards website and are communicated via the quarterly BRC Global Standards newsletter. This newsletter is sent to all certificated companies and certification bodies.
1.1.10	Where the site is certificated to the Standard, it shall ensure that announced recertification audits occur on or before the audit due date indicated on the certificate.
Interpretation	Audit due dates The audit due date is indicated on both the audit report and the certificate issued to all certificated sites. The responsibility for scheduling the next audit rests with the site. Announced audits may be taken in the 28 calendar days up to and including the audit due date. Late audits are likely to result in a gap in certification and will result in the award of a major non-conformity unless exceptional circumstances occur as identified in the audit protocol section of the Standard (Part III, section 2.8.2). This includes situations where the site is:
	 situated in a specific country or an area within a specific country where there is government advice not to visit and there is no suitable local auditor within a statutory exclusion zone that could compromise food safety or animal welfare in an area that has suffered a natural or unnatural disaster, rendering the site unable to produce or the auditor unable to visit affected by conditions that do not allow access to the site or restrict travel (e.g. heavy snow) producing seasonal products where production is delayed by a late start to the seasons (e.g. due to weather or product availability).
	Lack of personnel is not an acceptable reason for adjusting the audit date, as it is expected that the site will appoint adequate deputies and established systems of working to ensure the smooth operation of the site in the absence of individual managers. The undertaking of building work is also not an acceptable reason for delay unless the site is not in production while the building work is carried out.
	Where certification is not a customer requirement and the certificate has lapsed for more than 6 months, re-entry to the BRC certification scheme will be considered as a new application and the clause requiremen will not apply.
	Where a site has opted into one of the unannounced audit schemes, it becomes the responsibility of the certification body to ensure this requirement is met.
1.1.11	The most senior production or operations manager on site shall participate in the opening and closing meetings of the audit for certification to the Standard. Relevant departmental managers or their deputies shall be available as required during the audit.

CLAUSE	REQUIREMENTS
Interpretation	Senior management attendance at the audit The most senior production or operations managers on site (i.e. those who are responsible for the hands-on, daily running of the site) must participate in at least the opening and closing meetings of the audit.
	It may be the case that the most senior operations managers within the company are absent on the day of the audit because of other commitments; however, there must always be a nominated deputy available (clause 1.2.1). The objective is to ensure that non-conformities are effectively understood and agreed; therefore this site representative will need to be sufficiently senior to make decisions regarding any non-conformities and the corrective action to be taken.
1.1.12	The site's senior management shall ensure that the root causes of any non-conformities against the Standard identified at the previous audit have been effectively addressed to prevent recurrence.
Interpretation	Recurring non-conformities Non-conformities identified in previous certification audits must have been fully and effectively rectified and these will be checked during the current audit.
	Many sites have found it useful to retain copies of records and documents implicated by non-conformities with the audit records. This allows quick and easy reference to the specific document while reviewing, investigating and correcting the non-conformity. (The original copy of the document, should, of course, be returned to the appropriate place in the site's quality system.)
	An important aspect of this requirement is the need to ensure that the non-conformity does not recur. This should be achieved by the accurate identification of the cause(s) of the non-conformity (the root cause) and the introduction of effective preventive action.
	BRC Global Standards has published a guideline to understanding root cause analysis and preventive action. It explains some of the techniques available for identifying the cause of non-conformities and preventing them from recurring. The guideline may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).
	If effective preventive action has not been introduced a non-conformity may be raised against this clause at the next audit, in addition to a non-conformity against the clause that has the recurring issue.
1.1.13	The BRC Global Standards logo and references to certification status shall only be used in accordance with the conditions of use detailed in the audit protocol section (Part III, section 5.6) of the Standard.
Interpretation	Use of the BRC Global Standards logo Sites that have gained certification against any of the BRC Global Standards are entitled to demonstrate their pride in the achievement and use the BRC Global Standards certification logo for marketing purposes.

This means the logo can be used on websites, letter headers, business cards etc.

However, the BRC Global Standards logo is not a product certification mark, so it (or words stating that the product was produced in a BRC Global Standard certificated site) cannot be used on product packaging. The rules around logo use are detailed in the protocol of the Standard and further guidance is available from BRC Global Standards.

Where an auditor finds packaging with any BRC Global Standards logo or wording during an audit, they will raise a non-conformity.

1.2 ORGANISATIONAL STRUCTURE, RESPONSIBILITIES AND MANAGEMENT AUTHORITY

The company shall have a clear organisational structure and lines of communication to enable effective management of product safety, legality and quality.

Interpretation

The objective is to ensure that staff are clear who has responsibility for all aspects of the food safety and quality system and that the responsible person has the knowledge and ability to fulfil the role.

CLAUSE	REQUIREMENTS
1.2.1	The company shall have an organisation chart demonstrating the management structure of the company. The responsibilities for the management of activities which ensure food safety, integrity, legality and quality shall be clearly allocated and understood by the managers responsible. It shall be clearly documented who deputises in the absence of the responsible person.
Interpretation	Organisational charts and assignment of responsibilities An organisational chart must be available, clearly indicating reporting lines for all managers on the site and, where applicable, relationships to the company head office roles. The chart would normally be expected to show both a position and the named person occupying that position. Where the chart shows job titles only, other documents must indicate the person occupying each position.
	The chart or associated documentation needs to clearly indicate the responsibilities of each relevant member of staff with responsibility for the management of food safety, legality or quality. Examples include technical managers, quality assurance staff, managers accountable for overseeing production and cleaning activities (i.e. those responsible for ensuring the correct standards are maintained), any laboratory staff and product development teams.
	Responsibilities must be defined for key aspects of the food safety and quality management system, including, for example, decisions on corrective actions, non-conforming products, process deviations, finished product release, document control and customer complaints. It is usual for specific responsibilities to be defined within the job descriptions of key staff (especially for management and supervisors); however, they may instead be described within site procedures (e.g. responsibility for decisions on corrective action may be incorporated into the site's corrective action procedure).
	It must be clearly documented who is expected to deputise in the absence of a manager. Deputies would usually be identified on the organisational chart and/or in job descriptions, but documentation could also be in the form of an additional table. The responsibility may be assigned to either a more senior or more junior person, as long as the deputy has the knowledge and ability to adequately cover for the absent manager. Deputies may be appointed for the whole role or particular responsibilities may be deputised to different people, as long as this is clearly defined.
	The auditor will be looking for both documented responsibilities and evidence that the responsible person is able to fulfil the role (clause 7.1.7 requires the company to review the competencies of staff and ensure that any necessary training, mentoring or experience is provided).
1.2.2	The site's senior management shall ensure that all employees are aware of their responsibilities. Where documented work instructions exist for activities undertaken, the relevant employees shall have access to these and be able to demonstrate that work is carried out in accordance with the instructions.
Interpretation	Employees' roles and responsibilities The objective of this clause is to ensure that employees, including temporary staff and agency staff, are able to work effectively and ensure that food safety and quality are maintained. This will usually be established by the auditor discussing employees' jobs with the employees themselves during the audit.
	There is no requirement for a detailed job description; however, employees should be aware of their particular responsibilities.
	Where the role or an activity that makes up part of the role covers a food safety issue described within a procedure (e.g. a CCP or prerequisite programme), the employee must understand what is expected and be able to access the relevant procedure.

2 THE FOOD SAFETY PLAN - HACCP

FUNDAMENTAL

The company shall have a fully implemented and effective food safety plan incorporating the Codex Alimentarius HACCP principles.

Interpretation

To comply with section 2 of the Standard a systematic, science-based approach to the identification of potential food-borne hazards is required, together with the establishment of controls designed to prevent each hazard exceeding acceptable limits.

The purpose of these requirements is to create a plan to mitigate food safety hazards. The specific terminology used in the Standard, such as 'prerequisites' and 'critical control points' (CCPs), is intended to reflect the global terminology used to describe expectations. Sites are not required to use the specific terminology in the Standard; alternatives are acceptable providing it is evident that all the requirements have been fully met. For example, different terminology is used for legislative requirements in the US (the Food Safety Modernization Act) but this still incorporates all the requirements of the Standard and therefore of a HACCP or food safety plan.

Sites are advised to avoid having multiple plans with different terminology as this is administratively complex and unnecessary. (It may, of course, be appropriate to have multiple plans where a site produces different types of products with different product safety hazards, but common terminology should be used throughout.)

Via the BRC Academy, BRC Global Standards offers training on HACCP implementation. Details are available from **www.brcglobalstandards.com/training/courses/**

Background information on the Codex Alimentarius HACCP principles can be found at http://www.fao.org/fao-who-codexalimentarius/en/

2.1 THE HACCP FOOD SAFETY TEAM (EQUIVALENT TO CODEX ALIMENTARIUS STEP 1)

CLAUSE	REQUIREMENTS
2.1.1	The HACCP or food safety plan shall be developed and managed by a multi-disciplinary food safety team that includes those responsible for quality assurance, technical management, production operations, engineering and other relevant functions.
	The team leader shall have an in-depth knowledge of Codex HACCP principles (or equivalent) and be able to demonstrate competence, experience and training. Where there is a legal requirement for specific training, this shall be in place.
	The team members shall have specific knowledge of HACCP and relevant knowledge of products, processes and associated hazards.
	In the event of the site not having the appropriate in-house knowledge, external expertise may be used, but day-to-day management of the food safety system shall remain the responsibility of the company.
Interpretation	The HACCP food safety team (aligned with Codex Alimentarius Step 1) For a comprehensive HACCP or food safety plan to be established and maintained, it needs to be managed by a nominated team with suitable training, relevant skills and experience.
	Suitable training shall include the principles of the tool being used and be of sufficient duration. For example, BRC Global Standards auditors are required to undertake a 2-day, classroom-based HACCP course. Any format or delivery method of training is permitted; however, the outcome should be a suitably trained individual capable of executing a HACCP or food safety plan as part of their team.
	The number of HACCP food safety team members needs to be appropriate to the size and structure of the company, as the team will include representatives of each department with responsibility for the operation of the Standard. There will always be more than one person, since a single person does not constitute a 'team'. The team needs knowledge of the types of operations that are carried out at the site and the hazards these operations may present to the product.

CLAUSE REQUIREMENTS

It is good practice to document the team members within the study, with a summary of their roles within the company. Membership of the HACCP food safety team needs to be reviewed and, when necessary, updated (e.g. when job responsibilities change or personnel leave or join the company).

The team leader must be able to demonstrate competency and experience in HACCP/food safety processes. This can be shown by:

- the quality of the plan
- documented evidence of their qualification (e.g. successful completion of an industry-recognised HACCP training course)
- demonstrable, extensive experience in implementing or training HACCP.

The team leader may be either an appropriately qualified external consultant or an internal staff member.

Training records (see clause 7.1.6) need to demonstrate that adequate training has been given to all HACCP food safety team members. This may be achieved through, for example, an industry-recognised training course or good-quality internal training.

Where external expertise has been used in developing the HACCP or food safety plan, the site must demonstrate ownership of the identified requirements by ensuring that the day-to-day management of the food safety system remains the responsibility of the site.

At the audit, the competency and understanding of the HACCP/food safety plan team will be assessed, as well as the quality of the resultant HACCP or food safety plan. The site should also be able to establish the training and competence of any external consultant in HACCP/food safety principles.

Senior management commitment (clauses 1.1.1 to 1.1.13) is required to support the HACCP food safety team. This may be demonstrated by the presence of senior management within the team, policy statements referring to HACCP or food safety, or evidence within management review meetings that HACCP/food safety issues are discussed and reviewed.

The results of the HACCP or food safety plan must be integrated into the food safety and quality management system.

2.1.2

The scope of each HACCP or food safety plan, including the products and processes covered, shall be defined.

Interpretation

Scope of the HACCP or food safety plan

The scope of the HACCP or food safety plan must be identified. The scope should describe all the products and processes to be included within the study. In sites with a small range of similar products, it may be possible to incorporate all of the products and processes into a single HACCP or food safety plan; however, where there is a wide range of different products or processes with different hazards, it is likely that the site will need to use more than one plan.

The format of these plans is not prescribed by the Standard; various formats are acceptable as long as the scope for each plan is clearly defined and all activities and products are covered within the processes. For example, a HACCP or food safety plan may cover each group of products with similar process characteristics, or the plan may be split into 'modules' which cover specific process steps; these modules can then be used in a 'mix and match' structure to create a HACCP or food safety plan for any given product.

2.2 PREREQUISITE PROGRAMMES

CLAUSE **REQUIREMENTS** The site shall establish and maintain environmental and operational programmes 2.2.1 necessary to create an environment suitable to produce safe and legal food products (prerequisite programmes). As a guide these may include the following, although this is not an exhaustive list: cleaning and sanitising pest management maintenance programmes for equipment and buildings personal hygiene requirements staff training purchasing transportation arrangements processes to prevent cross-contamination allergen controls. The control measures and monitoring procedures for the prerequisite programmes must be clearly documented and shall be included within the development and reviews of the HACCP or food safety plan.

Interpretation

Prerequisites

The prerequisites are the basic environmental and production conditions necessary for the manufacture of safe food and the control of generic hazards.

Although the prerequisites are usually covered by day-to-day activities such as good manufacturing or hygiene practices, it is vital that they work effectively and to the correct standards as:

- the prerequisite programme needs to provide a solid base on which the rest of the HACCP or food safety plan can be developed
- the company is relying on the prerequisite activities to mitigate the identified hazards and deliver safe product (e.g., if a site identifies cleaning as a prerequisite, then it relies on the cleaning activities to adequately remove food residues and dirt that might otherwise result in hazards such as allergen cross-contamination or microbiological contamination).

Therefore there should be a whole work-stream behind each identified prerequisite to ensure that the relevant activity, procedures and policies are in place, that they are working correctly and that they continue to deliver the level of control required.

Although the prerequisite programme is expected to be effective in achieving the level of control required to ensure food safety, it is not a requirement that a documented validation of every prerequisite is undertaken, as prerequisite programmes typically cover a wide range of general environmental controls, often with results that are not quantifiable. However, where a prerequisite programme is used to manage a specific hazard (e.g. cleaning regimes used to prevent allergen cross-contamination), there needs to be a documented validation that the prerequisite controls the identified hazard (see clause 2.7.3 for further details regarding the validation). Some companies prefer to differentiate these prerequisites that manage specific hazards from other prerequisites by referring to them as operational prerequisites (oPRPs).

Sites that need to meet the requirements of the US Food Safety Modernization Act (FSMA) should note that they must ensure that preventive controls are subject to validation and verification. Some of these controls may cover activities that have traditionally formed part of the prerequisite programme. Later sections of the Standard provide detail on the requirements for effective management of some specific prerequisites, including cleaning (section 4.11), pest management (section 4.14) and training (section 7.1).

Good practice is to review the prerequisite programmes and their management. The frequency of this review should be based on risk, but it could be included, for example, in the annual review of the HACCP or food safety plan.

2.3 DESCRIBE THE PRODUCT (EQUIVALENT TO CODEX ALIMENTARIUS STEP 2)

CLAUSE REQUIREMENTS A full description for each product or group of products shall be developed, which includes all relevant 2.3.1 information on food safety. As a guide, this may include the following, although this is not an exhaustive list: • composition (e.g. raw materials, ingredients, allergens, recipe) origin of ingredients • physical or chemical properties that impact food safety (e.g. pH, α_{u}) • treatment and processing (e.g. cooking, cooling) • packaging system (e.g. modified atmosphere, vacuum) storage and distribution conditions (e.g. chilled, ambient) maximum safe shelf life under prescribed storage and usage conditions. Interpretation **Product description** A full description of the product is required to ensure that all aspects that could potentially affect food safety are considered. The Standard gives guidance on the factors that may be considered: composition (e.g. raw materials or ingredients used, allergens, recipe) origin of the ingredients (e.g. climatic conditions, culture or food safety standards may make some countries a greater risk than others) physical or chemical properties that impact food safety (e.g. pH or a...) • treatment and processing conditions (e.g. cooking or chilling) product packaging system (e.g. modified atmosphere, vacuum packing or canning) • storage and distribution conditions (e.g. chilled, frozen or ambient) • maximum safe shelf life under prescribed storage and usage conditions. Product groups can be used where the products are similar (e.g. different pack sizes). However, where significantly different products (e.g. coated and non-coated meat products) are manufactured, these are to be treated as separate products or groups. All relevant information needed to conduct the hazard analysis shall be collected, maintained, documented 2.3.2 and updated. The company will ensure that the HACCP or food safety plan is based on comprehensive information sources, which are referenced and available on request. As a quide, this may include the following, although this is not an exhaustive list: • the latest scientific literature historical and known hazards associated with specific food products relevant codes of practice recognised guidelines • food safety legislation relevant for the production and sale of products

Interpretation

Sources of information

customer requirements.

Up-to-date background information must be taken into account when preparing the HACCP or food safety plan. Therefore, suitable information must be collated and maintained.

There are many sources of information, particularly on the internet; for example, Codex Alimentarius, European Food Safety Authority, US Food and Drug Administration, or the Rapid Alert System for Food and Feed (RASFF). Sources of information must be referenced in the HACCP or food safety plan and be recoverable or available on request (using an internet search engine to find the information during an audit is not acceptable, as this implies that the information was not collected and maintained for use during the development of the HACCP or food safety plan). A list of legislation and codes of practice referenced may be helpful.

Many membership organisations provide useful information. Where membership information is referenced, this also needs to be available on site (either electronically or as hard copy). The Standard gives some guidance on the types of information that may be considered in developing the HACCP or food safety plan. These include:

- the latest scientific literature
- historical and known hazards associated with specific food products (good practice is to be as specific as possible, giving, for example, the name of the micro-organism(s) that are known hazards to the product, rather than just listing 'bacteria')

CLAUSE	REQUIREMENTS
	 relevant codes of practice recognised guidelines food safety legislation relevant for the production and sale of products in destination countries, states or territories customer requirements.

2.4 IDENTIFY INTENDED USE (EQUIVALENT TO CODEX ALIMENTARIUS STEP 3)

CLAUSE	REQUIREMENTS
2.4.1	The intended use of the product by the customer, and any known alternative use, shall be described, defining the consumer target groups, including the suitability of the product for vulnerable groups of the population (e.g. infants, elderly, allergy sufferers).
Interpretation	Identify the use The HACCP food safety team needs to consider and document the intended use of the products by the customer and the ultimate consumer to ensure all the risks have been assessed. For example, the team should consider:
	 the target population (e.g. does this include high-risk groups such as infants, elderly people or allergy sufferers?) handling and preparation (e.g. will the product be consumed without further cooking?) the customer supply chain storage (e.g. frozen, or the requirement for chilled storage after opening the pack).
	Where there is a known alternative use for a product, including the potential for a customer or consumer to misuse or mistreat the product in a way not intended by the manufacturer, this information should be included in the description in the HACCP assessment so that any implications can be considered as part of the subsequent hazard analysis. For example, where a product looks ready to eat (but requires cooking) there is the potential for a consumer to insufficiently cook the product.

2.5 CONSTRUCT A PROCESS FLOW DIAGRAM (EQUIVALENT TO CODEX **ALIMENTARIUS STEP 4)**

CLAUSE	REQUIREMENTS
2.5.1	A flow diagram shall be prepared to cover each product, product category or process. This shall set out all aspects of the food process operation within the HACCP or food safety plan scope, from raw material receipt through to processing, storage and distribution. As a guide, this should include the following, although this is not an exhaustive list:
	 plan of premises and equipment layout raw materials, including introduction of utilities and other contact materials (e.g. water, packaging) sequence and interaction of all process steps outsourced processes and subcontracted work potential for process delay rework and recycling low-risk/high-risk/high-care area segregation finished products, intermediate/semi-processed products, by-products and waste.

CLAUSE REQUIREMENTS

Interpretation

Process flow diagram

An accurate flow diagram indicating all the process steps, including all inputs and outputs, needs to be constructed for each HACCP or food safety plan. This may be achieved with a single diagram, or it could be in a modular form with several documents compiled to provide the complete information (in this situation it must clearly identify the interaction between the process steps). The Standard lists guidance on the points to consider and include when developing the flow diagram; for example:

- a plan of the premises and equipment layout to facilitate consideration of cross-contamination risks (e.g., allergen control)
- raw materials it should be clear where raw materials are stored and the routes they take into the production area; this includes the introduction of utilities and other contact materials (e.g. water or packaging)
- sequence and interaction of all process steps (e.g. method of transportation between each step)
- outsourced processes and subcontracted work
- potential for process delay (i.e. how products or ingredients will be handled if a delay occurs)
- rework and recycling
- low-risk/high-risk/high-care segregation (i.e. clearly indicating where the different production zones are located)
- finished products, intermediate/semi-processed products, by-products and waste (e.g. where waste products leave the production process and the storage of intermediates and finished products).

Clause 3.2.1 of the Standard requires the site to have an effective document control system. Signing and dating the approved process flow diagram is one method of demonstrating that this is occurring.

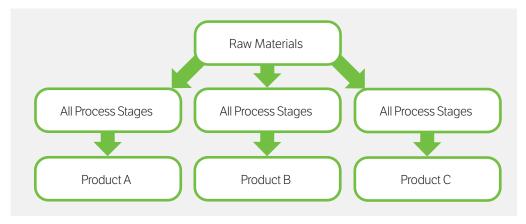

Examples

There is no set pattern or format for the diagram. However, it is important to show all the steps in the process, from raw materials through to final products.

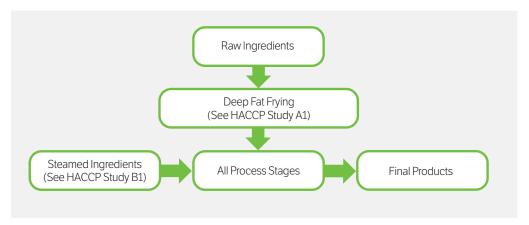

Example of a process flow diagram: linear

All products must be covered in the diagram, so if your site has a wide range of similar products or processes, a modular option may be preferable. Otherwise a separate linear diagram is needed for each product; i.e. 20 products would need 20 linear process flow diagrams.

Example of a modular process flow diagram (1)

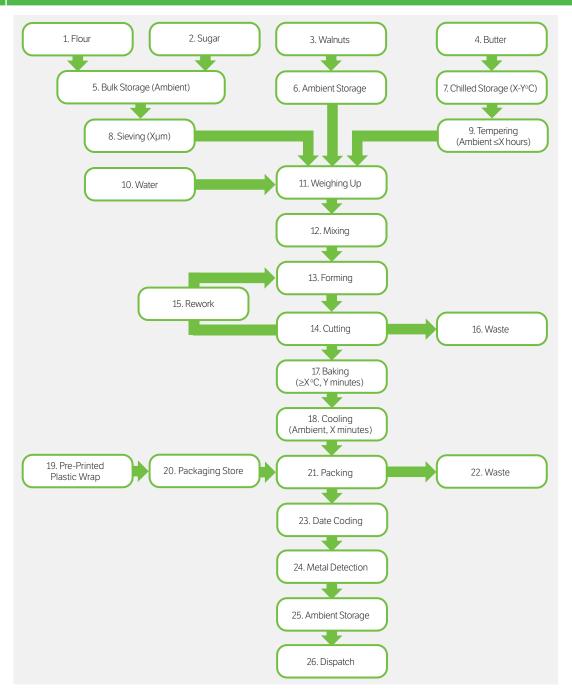

Example of a modular process flow diagram (2)

If you use a modular or generic diagram, take care to ensure that all steps and all products are included in the diagram. If your site manufactures multiple products that are considerably different or require different processes, you will need to have several separate diagrams.

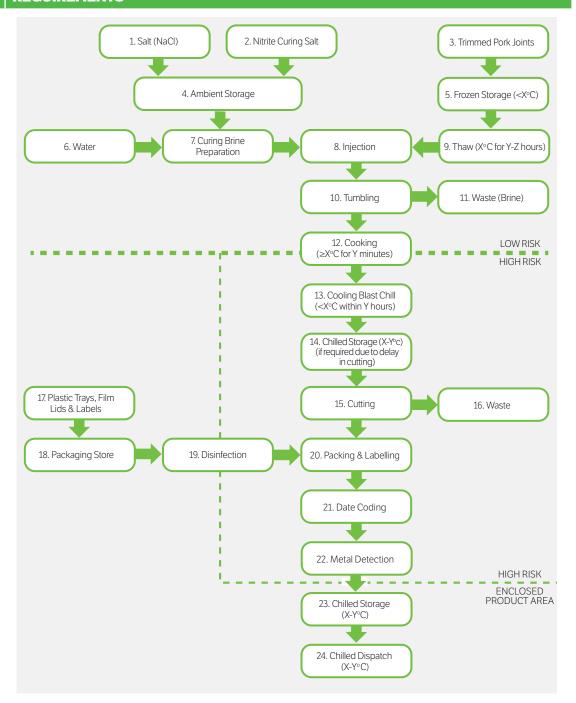

In addition to the process steps, the diagram needs to contain:

- all raw materials used in the manufacture of the product(s), including the introduction of utilities and other contact materials (e.g. water or packaging)
- details of any outsourced or subcontracted process (i.e. any activity that is part of the production process but does not occur on site)
- rework or recycling
- low-risk, high-care and high-risk segregation
- routes taken by waste products
- all finished products, intermediates, semi-processed products or by-products.

Example of a completed process flow diagram: walnut biscuit

Example of a completed process flow diagram: cooked cured meat

2.6 VERIFY FLOW DIAGRAM (EQUIVALENT TO CODEX ALIMENTARIUS STEP 5)

CLAUSE	REQUIREMENTS
2.6.1	The HACCP food safety team shall verify the accuracy of the flow diagrams by on-site audit and challenge at least annually. Daily and seasonal variations shall be considered and evaluated. Records of verified flow diagrams shall be maintained.
Interpretation	Verifying the flow diagram The flow diagram shall be verified as accurate. A member of the HACCP food safety team who is based at the site, part of the team or the whole team must check that the flow diagram is accurate 'by on-site audit and challenge'. This may be achieved using a physical walk-through of the process within the production area. A report of the activity and any findings will help to demonstrate that this has been completed.
	During the BRC Global Standards audit, the auditor will undertake part or all of this process to confirm the accuracy of the documented process flow diagram.
	It is vital that the process flow diagram remains up to date; therefore verification should occur whenever there is a review of the HACCP or food safety plan (e.g. whenever there is a change to the plan or operational activity) and at least once per year. It is important that any daily or seasonal variations are considered during the verification process (e.g. the production of a Christmas range that uses ingredients or processes not used during the rest of the year).
Further guidance	The importance of keeping good records Your site should maintain full records of the diagrams and all verification activities. A verification record could include a fully annotated diagram showing, for example:
	 the date and time of the verification the product(s) being manufactured at the time the activity was observed any amendments or alterations that were noted.
	Alternatively, a separate report could be produced in the format of an internal audit. The records should also be signed to confirm who completed the verification.
Quick tips	 Ensure all relevant information is incorporated in the diagram. Ensure all ingredients are incorporated, including water, additives and packaging. Consider all shifts worked, including night or weekend production. Consider seasonal or occasional production activities.

2.7 LIST ALL POTENTIAL HAZARDS ASSOCIATED WITH EACH PROCESS STEP, CONDUCT A HAZARD ANALYSIS AND CONSIDER ANY MEASURES TO CONTROL IDENTIFIED HAZARDS (EQUIVALENT TO CODEX ALIMENTARIUS STEP 6, PRINCIPLE 1)

CLAUSE	REQUIREMENTS
2.7.1	The HACCP food safety team shall identify and record all the potential hazards that are reasonably expected to occur at each step in relation to product, process and facilities. This shall include hazards present in raw materials, those introduced during the process or surviving the process steps, and consideration of the following types of hazard:
	 microbiological physical contamination chemical and radiological contamination fraud (e.g. substitution or deliberate/intentional adulteration) malicious contamination of products allergen risks (see section 5.3).
	It shall also take account of the preceding and following steps in the process chain.

CLAUSE

REQUIREMENTS

Interpretation

List of potential hazards

It is expected that the list will include specific hazards. The Standard provides examples of those that should be considered, including:

- specific micro-organisms (e.g. E. coli or Salmonella)
- specific chemicals (e.g. veterinary residues, pesticides or radiological contaminants)
- cleaning chemicals
- machinery lubricants
- specific foreign bodies (e.g. glass, metal or plastic)
- specific allergens (e.g. peanuts or egg)
- the potential for fraud and/or adulteration
- malicious tampering with the product or processes.

Consideration must be given to all the sources of potential hazards. These could include raw materials, processes and the factory environment. The process flow diagram is a useful tool in considering the potential risks at each stage of production.

There must be a description of each hazard and its sources – one hazard may have several potential sources and occur at more than one point in the process. This is important to ensure that effective controls for each source of hazard are established in the subsequent steps of the process.

2.7.2

The HACCP food safety team shall conduct a hazard analysis to identify hazards which need to be prevented, eliminated or reduced to acceptable levels. Consideration shall be given to the following:

- likely occurrence of hazard
- severity of the effects on consumer safety
- vulnerability of those exposed
- survival and multiplication of micro-organisms of specific concern to the product
- presence or production of toxins, chemicals or foreign bodies
- contamination of raw materials, intermediate/semi-processed product, or finished product.

Where elimination of the hazard is not practical, justification for acceptable levels of the hazard in the finished product shall be determined and documented.

Interpretation

Hazard analysis

Any hazards identified in clause 2.7.1 must be evaluated against the criteria detailed in clause 2.7.2, considering the consequences of the identified hazard. You must therefore take into account:

- the likely occurrence of the hazard
- the severity of the effects on consumer safety
- the vulnerability of those exposed
- the survival and growth of micro-organisms (i.e. those of concern to the product(s) within the scope of the HACCP or food safety plan)
- the presence or production of toxins, chemicals or foreign bodies
- contamination of raw materials, intermediates, semi-processed product or finished product.

Evidence of the decisions and the decision-making process must be kept within the HACCP or food safety plan.

There are a range of tools that may assist with the evaluation of hazards (e.g. quadrant graphs, scoring systems, logic tables or decision trees). The team may choose to use these tools but should keep a record of any that are deployed. Such tools may also help in establishing CCPs.

It is useful to remember that the quality of the output from the assessment depends on the quality of the data or evidence used. The hazard analysis should, wherever possible, be based on demonstrable evidence such as documented validation studies, trend analysis and science-based literature. Where this information is not available at the site, it may be necessary for the site to obtain it from suppliers or reputable external sources to establish the likelihood or severity of the specific hazards.

Where elimination of a hazard is not possible, acceptable levels need to be defined. Reference should be made to legal requirements or scientific evidence to justify the acceptable levels (e.g. microbiological standards or presence of mycotoxins).

CLAUSE	REQUIREMENTS			
2.7.3	The HACCP food safety team shall consider the control measures necessary to prevent or eliminate a food safety hazard or reduce it to an acceptable level. Where the control is achieved through existing prerequisite programmes, this shall be stated and the adequacy of the programme to control the specific hazard validated. Consideration may be given to using more than one control measure.			
Interpretation	Control measures Control measures required to reduce or eliminate the specific hazards (i.e. each hazard identified in clause 2.7.1) must be established. Any hazard that cannot be eliminated must have control measures designed to reduce it to an acceptable level of presence. This acceptable level (e.g. setting a target of <100 cfu/g of Staphylococcus aureus in finished product) needs to be justified. Industry guidelines, codes of practice, legislation etc. can help to establish and justify these levels.			
	Where control is achieved via the prerequisite programme, reference must be made in the HACCP or food safety plan to the specific prerequisite that controls the hazard. Although the prerequisite programme is expected to achieve the required level of control, it is not necessary to undertake a documented validation of every prerequisite, as prerequisite programmes typically cover a wide range of general environmental controls, often with results that are not quantifiable. However, where a prerequisite programme is used to manage a specific hazard (e.g. cleaning regimes used to prevent allergen cross-contamination), there needs to be a documented validation that the prerequisite controls the identified hazard.			
Examples	Prerequisites that require validation include:			
	 control of allergen cross-contamination by cleaning the production equipment. Evidence is required that the cleaning regime can effectively remove the allergen (examples of how this might be achieved are given in the guidance to clause 5.3.8) chilled storage conditions. The defined storage temperature must be validated by reference to technical literature, confirming the control of growth of relevant spoilage or food poisoning organisms. The storage facility must be validated as being capable of consistently delivering the defined temperature. 			
	Prerequisites used to control specific hazards must be subject to routine verification and monitoring, and records should detail the control measures and monitoring procedures used.			

2.8 DETERMINE THE CRITICAL CONTROL POINTS (CCPS) (EQUIVALENT TO CODEX ALIMENTARIUS STEP 7, PRINCIPLE 2)

CLAUSE	REQUIREMENTS			
2.8.1	For each hazard that requires control, control points shall be reviewed to identify those that are critical. This requires a logical approach and may be facilitated by use of a decision tree. Critical control points (CCPs) shall be those control points which are required in order to prevent or eliminate a food safety hazard or reduce it to an acceptable level. If a hazard is identified at a step where control is necessary for safety but the control does not exist, the product or process shall be modified at that step, or at an earlier step, to provide a control measure.			
Interpretation	Determine the critical control points – Codex Alimentarius Step 7, Principle 2 Each control measure must be examined to identify which are critical (i.e. to identify the points at which control can be applied). This is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.			
	Records must be available showing how this has been conducted and how decisions have been reached. A two- or four-question decision tree may be useful and, where this has been used, a copy of the tree and the results of the questions must be recorded. See Appendix 1 for an example of a decision tree.			
	If a hazard has been identified as critical but there is no control measure at that step or any other, the product or process should be modified so that a suitable control measure can be incorporated either at this step or at an earlier point in the process.			
	Sites working in accordance with the US Food Safety Modernization Act (FSMA) are likely to find that the preventive controls required by that legislation include all of the controls that would normally be identified as CCPs using a HACCP system.			
	Auditors shall be looking to confirm that the site has identified the correct points at which control should be exercised by the appropriate control mechanisms.			

2.9 ESTABLISH CRITICAL LIMITS FOR EACH CCP (EQUIVALENT TO CODEX ALIMENTARIUS STEP 8, PRINCIPLE 3)

Interpretation

Once the HACCP or food safety team has identified all the relevant CCPs, it must then identify critical limits. The critical limit is the point that separates safe from unsafe or acceptable from unacceptable product.

Some critical limits are defined by legislation; however, many will require experimental results, the advice of appropriate industry specialists or consideration of customer requirements.

CLAUSE	REQUIREMENTS					
2.9.1	For each CCP, the appropriate critical limits shall be defined in order to identify clearly whether the process is in or out of control. Critical limits shall be:					
	 measurable wherever possible (e.g. time, temperature, pH) supported by clear guidance or examples where measures are subjective (e.g. photographs). 					
Interpretation	Critical limits All identified CCPs must have defined critical limits.					
	Wherever possible the criteria used should be objective (i.e. measurable), such as the temperature, time, moisture level, pH and $a_{\rm w}$.					
	Where objective criteria are not available, subjective parameters can be used. These may include sensory parameters such as visual appearance and texture, but they must be supported by clear guidance or examples. Photographs of acceptable and unacceptable limits or product samples for comparison could be shown as examples to staff at process control points.					
	Details on how the critical limits have been determined must be documented; these may include industry best practice, legislation or validation studies undertaken by the company.					
2.9.2	The HACCP food safety team shall validate each CCP. Documented evidence shall show that the control measures selected and critical limits identified are capable of consistently controlling the hazard to the specified acceptable level.					
Interpretation	Validation and documentation of critical limits Documented evidence must be available showing how the control measures for CCPs and other controls, where appropriate, have been validated to ensure they control, reduce or eliminate the hazard to the specified critical limit.					
	Validation must demonstrate that if the control measures are followed as specified and the critical limits are met (at minimum and maximum levels where a range is indicated), a consistently safe product will be produced. Evidence could come from professional bodies, trade associations, historical processing data, scientific and technical literature or legislation. In addition, scientifically valid experimental or pilot plant trial data or exercises, such as challenge testing, may be required to confirm the capability of the process.					

2.10 ESTABLISH A MONITORING SYSTEM FOR EACH CCP (EQUIVALENT TO CODEX ALIMENTARIUS STEP 9, PRINCIPLE 4)

Interpretation

Monitoring is a planned set of checks or measurements for each CCP to ensure it is consistently meeting the identified critical limit. Monitoring must be recorded in terms of both the procedures to be followed and the results obtained.

CLAUSE	REQUIREMENTS					
2.10.1	A monitoring procedure shall be established for each CCP to ensure compliance with critical limits. The monitoring system shall be able to detect loss of control of CCPs and, wherever possible, provide information in time for corrective action to be taken. As a guide, consideration may be given to the following, although this is not an exhaustive list:					
	 online measurement offline measurement continuous measurement (e.g. thermographs, pH meters etc.). 					
	Where discontinuous measurement is used, the system shall ensure that the sample taken is representative of the batch of product.					
Interpretation	Monitoring systems Each CCP needs to be monitored to ensure the established limits are not exceeded. This can be achieved by observing or measuring the CCP at scheduled intervals or by the use of automated continuous measurement systems.					
	A monitoring procedure must be established for each CCP. At a minimum, this should include:					
	 the CCP to which the procedure relates the staff (or staff role) responsible for monitoring the CCP (clause 1.2.1 requires the staff responsible for product safety activities to be documented) training requirements for responsible staff the frequency at which the monitoring is completed instructions on how the monitoring is completed the requirements for record-keeping (clause 2.10.2) the critical limit(s). 					
	Monitoring must be able to detect variation, which may result in limits being broken if no remedial action is taken. Wherever possible monitoring must be sufficiently frequent to ensure that any necessary remedial action can be taken in adequate time so that there is no risk to the product and that no potentially affected product is released for sale or dispatched to the customer.					
	Methods used may include online or offline measurements and may be continuous or discontinuous.					
2.10.2	Records associated with the monitoring of each CCP shall include the date, time and result of measurement and shall be signed by the person responsible for the monitoring and verified, when appropriate, by an authorised person. Where records are in electronic form, there shall be evidence that records have been checked and verified.					
Interpretation	Monitoring system records The results of monitoring activities must be recorded. At a minimum, these records must include:					
	 date and time when the measurement was made the result the signature of the individual conducting the monitoring the signature of the individual (e.g. the line manager) checking and verifying the record. This verification should be completed at appropriate frequencies which, depending on working practices, may be at identified points during the day (e.g. at the end of the shift) rather than every time a measurement is made. 					

2.11 ESTABLISH A CORRECTIVE ACTION PLAN (EQUIVALENT TO CODEX **ALIMENTARIUS STEP 10, PRINCIPLE 5)**

CLAUSE	REQUIREMENTS
2.11.1	The HACCP food safety team shall specify and document the corrective action to be taken when monitored results indicate a failure to meet a control limit, or when monitored results indicate a trend towards loss of control. This shall include the action to be taken by nominated personnel with regard to any products that have been manufactured during the period when the process was out of control.
Interpretation	Establish a corrective action plan A documented procedure needs to be established, detailing the actions to be taken when monitoring indicates that limits have been exceeded or when trends suggest they may be exceeded if no remedial action is taken.
	The procedure must include:
	 authorised personnel – identify the authorised personnel who can make decisions about product produced where limits have been exceeded and the corrective actions to be taken immediate remedial action to be taken quarantine procedures – give instructions on how implicated products that have passed through the process and may therefore have exceeded the limits are handled and/or stored until their safety status is established (e.g. products that have been metal-detected since the last satisfactory metal detector check). The handling and storage procedure must ensure that implicated product cannot enter production or be distributed to customers unless it has been confirmed as safe and released by the authorised staff disposal procedures for unsafe products additional actions that may be required (e.g. alternative processing, increased monitoring etc.).
	When investigation shows that the implicated product is safe and can be released to customers it may be necessary to review the critical limit, as the 'safe' product implies that the critical limit has not been set at the correct value.

2.12 ESTABLISH VERIFICATION PROCEDURES (EQUIVALENT TO CODEX **ALIMENTARIUS STEP 11, PRINCIPLE 6)**

CLAUSE	REQUIREMENTS				
2.12.1	Procedures of verification shall be established to confirm that the HACCP or food safety plan, including controls managed by prerequisite programmes, continues to be effective. Examples of verification activities include:				
	 internal audits review of records where acceptable limits have been exceeded review of complaints by enforcement authorities or customers review of incidents of product withdrawal or recall. 				
	Results of verification shall be recorded and communicated to the HACCP food safety team.				
Interpretation	Establish verification procedures The HACCP or food safety plan, including controls managed by prerequisites, must be verified to ensure that it remains effective.				
	Verification requires objective evidence that the specified requirements are being met. Examples of activity that can be included in verification studies are:				
	 internal audits (e.g. to ensure the correct procedures and work instructions are in use and that monitoring frequencies are correct) review and trending of records (e.g. CCP monitoring records) review of complaints by enforcement authorities or customers review of incidents (e.g. product withdrawal or recall). 				
	The results of this verification must be documented and communicated to the HACCP or food safety team as part of the review process.				
	Verification should be completed to a planned schedule.				

2.13 HACCP DOCUMENTATION AND RECORD-KEEPING (EQUIVALENT TO CODEX ALIMENTARIUS STEP 12, PRINCIPLE 7)

CLAUSE	REQUIREMENTS					
2.13.1	Documentation and record-keeping shall be sufficient to enable the site to verify that the HACCP and food safety controls, including controls managed by prerequisite programmes, are in place and maintained.					
Interpretation	HACCP documentation Records must be kept to demonstrate that the HACCP or food safety plan, including the prerequisite programmes, is fully implemented. This must include all the steps in creating and reviewing the plan, records of control and monitoring procedures, and training records of staff.					

2.14 REVIEW THE HACCP PLAN

CLAUSE	REQUIREMENTS			
2.14.1	The HACCP food safety team shall review the HACCP or food safety plan and prerequisite programmes at least annually and prior to any changes which may affect food safety. As a guide, these may include the following, although this is not an exhaustive list:			
	 change in raw materials or supplier of raw materials change in ingredients/recipe change in processing conditions, process flow or equipment change in packaging, storage or distribution conditions change in consumer use emergence of a new risk (e.g. known adulteration of an ingredient or other relevant, published information, such as the recall of a similar product) review following a recall new developments in scientific information associated with ingredients, process or product. 			
	Appropriate changes resulting from the review shall be incorporated into the HACCP or food safety plan and/or prerequisite programmes, fully documented and the validation recorded.			
	Where appropriate, the changes shall also be reflected in the company's product safety policy and food safety objectives.			
Interpretation	Review of the HACCP plan The HACCP or food safety plan and associated prerequisite programmes must be reviewed regularly, at a minimum of once a year, even if there have been no changes to the product range or processing methods. Some or all of the plan should be reviewed whenever there is a significant change.			
	Changes that may affect product safety, such as those listed in clause 2.14.1, need to be evaluated in the context of the plan before they are introduced, and the plan amended as necessary. A procedure could be documented that lists the activities or changes which trigger a HACCP review, but this would have to be backed up by documented evidence that the review has actually been carried out (e.g. by documenting minutes of the meeting or an agreed action plan).			

3 FOOD SAFETY AND QUALITY MANAGEMENT SYSTEM

3.1 FOOD SAFETY AND QUALITY MANUAL

The company's processes and procedures to meet the requirements of this Standard shall be documented to allow consistent application, facilitate training, and support due diligence in the production of a safe product.

Interpretation

A well-documented, systematic management system forms the basis for the product and process controls necessary to produce safe products, meet the requirements of the Standard, meet customer specifications and enable staff to be trained and informed.

CLAUSE	REQUIREMENTS						
3.1.1	The site's procedures, working methods and practices shall be collated in the form of a printed or electronic quality manual.						
Interpretation	The food safety and quality manual Policies, procedures and work instructions must be in place, easily retrievable and available where needed, and must cover the requirements of the Standard. These documents must be collated into one or more quality manuals which form the reference point for all documents included in the food safety and quality system.						
	These documents may exist on paper (i.e. as hard copy) or may be controlled on an electronic system. In either case, they should be easy to follow and kept up to date.						
	In a small, simple operation, the manual may contain the majority of the procedures controlling the processes. In a complex operation it may contain the headline policies and indicate where more detailed operating instructions can be found.						
	The manual should include an overview of how the company's policies and procedures are organised. This organisation should be understood by those using the documents and easily demonstrated. Where the site is part of a company governed by a head office, the interaction between the site's documented system and that of the other sites and the head office should be clear. All policies and procedures necessary for the operation of the site being assessed must be available at that site.						
	There is no requirement for sites to have a quality manual that is numbered in accordance with the BRC Global Standards' numbering system.						
3.1.2	The food safety and quality manual shall be fully implemented and the manual or relevant components shall be readily available to relevant staff.						
Interpretation	Availability of the manual to staff The objective of this requirement is to ensure that key staff have access to up-to-date policies and procedures at all times and in the most appropriate format. For example, the incident management procedure should be available to the relevant team members via internet link, hard copy or other off-site format.						
	Staff needing such documents as part of their role within the company must always have access to them. During the audit the procedures documented in the manual will be evaluated against the actual practices on the site, with the expectation that they are followed correctly.						
3.1.3	All procedures and work instructions shall be clearly legible, unambiguous, in appropriate languages and sufficiently detailed to enable their correct application by appropriate staff. This shall include the use of photographs, diagrams or other pictorial instructions where written communication alone is not sufficient (e.g. there are issues of literacy or foreign language).						

CLAUSE **REQUIREMENTS** Interpretation Clear procedures and work instructions for staff Procedures and work instructions must be documented in a clear and unambiguous format. Anyone using an authorised document must be able to understand its relevance, what it is for and how to use it. Evidence is required to demonstrate that staff clearly understand the procedures as this will be challenged by the auditor. Consideration may be given to providing procedures in appropriate languages, either written or oral, to ensure staff understand the documents and their role. Where translations are used, a record should be kept of who translated the information into which language(s). Both the translator and the recipient staff should sign the training record to indicate that the translated version has been understood. Documentation must include the use of photographs, diagrams or other pictorial instructions where written communication alone is not sufficient. For example, diagrams added to cleaning instructions can show clearly which pieces of equipment to remove or focus on. Signs and pictures can be particularly useful for communicating personal hygiene and protective clothing requirements.

3.2 DOCUMENT CONTROL

The company shall operate an effective document control system to ensure that only the correct versions of documents, including recording forms, are available and in use.

Interpretation

Documents must be effectively controlled to ensure that staff are working with the most up-to-date information and to minimise the potential for mistakes. Documents include policies, procedures, work instructions, records, forms, specifications, data lists and any information that is written down and defined. They may be available on paper (i.e. as 'hard copy') or in electronic format.

Key documents found to be in use during the audit that have not been properly authorised or are not the correct version may lead to a non-conformity.

CLAUSE	REQUIREMENTS				
3.2.1	The company shall have a procedure to manage documents which form part of the food safety and quality system. This shall include:				
	 a list of all controlled documents indicating the latest version number the method for the identification and authorisation of controlled documents a record of the reason for any changes or amendments to documents the system for the replacement of existing documents when these are updated. 				
	Where documents are stored in electronic form these shall also be:				
	stored securely (e.g. with authorised access, control of amendments, or password protected)backed up to prevent loss.				
Interpretation	Documented management system All documents in use need to be properly authorised and must be the correct version.				
	The Standard requires the site to have a documented procedure that describes the method by which documents are controlled and managed. The procedure needs to include instructions on how the following features of the document management system are controlled:				
	 responsibilities for the management of the system the list of all controlled documents, indicating the current version number and the allocation of controlled copies of the document (see below) identification of controlled documents (e.g. document ID, issue date, version number) 				

records of the reason for any change(s) (see below)method of rescinding and replacing documents.

REQUIREMENTS

In order to demonstrate the control of document issue, it is necessary to maintain a register of all controlled documents, their allocation and issue status. Where the controlled documents are all contained on an electronic system, it is usual for printed versions to be marked as uncontrolled. Each copy must be authorised (e.g. with a signature or stamp) to show it is for use, and each must be given a version number so that out-of-date documents can be identified and removed. This must be evidenced by the fact that all documents in use are the most up-to-date versions.

Where documents are maintained electronically, the site is required to ensure that they are stored securely and cannot be amended by unauthorised persons; for example, by using individual passwords or security swipe cards. This includes backing them up appropriately to ensure no data is lost. The auditor will ask to see evidence (e.g. a procedure) that the site has an effective back-up process, rather than auditing that the back-up contains all the relevant files.

The methodology or type of electronic storage is not specified. The site may choose to use an internal server to store data; or it may use cloud services, which are generally considered to be secure and backed up, providing there is control of authorised/authenticated users. When a document is changed, a record needs to be made of the change and the reason for it. This can be achieved by keeping a copy of the previous version with the reason for the change written on it, or by keeping a history of amendments. Consideration should also be given to the most effective method of communicating the changes to staff; for example, by highlighting the change within the new document.

Further guidance

The aims of a document control procedure

The control of all documents within food safety and quality systems (for both external and internal use) is important to ensure all staff consistently apply the correct, up-to-date procedures.

This requirement is not there to create extra bureaucracy but to help you effectively control your documents. By having a document control procedure in place you can ensure:

- documents are kept up to date
- all staff are working with the relevant version
- the potential for mistakes caused by multiple versions of a document is minimised
- information is provided in a consistent form that can be easily used
- information is retained (e.g. production records) that could help solve a problem or non-conformity.

How to put a document control procedure in place

Your site must have a documented procedure that describes how documents are controlled and managed. This will include:

- identification of the individual(s) responsible for management of the system (i.e. who is authorised to issue or amend documents). This might be someone with the authority to instigate and maintain the system
- the list of all controlled documents
- methods of identification of controlled documents
- records regarding the reasons for any changes
- the method of collecting and replacing documents.

List of documents

Your site needs a list of all the documents within the food safety and quality system. Typically this will include:

- the document identification or number. The Standard does not set out how you should identify your documents, but an example format would be using sequentially numbered documents or an initial letter (often representing a department or activity) followed by a number (e.g. P0123)
- the document title. Use a concise title that clearly explains the purpose or content of the document (e.g. 'metal detector check procedure')
- the current issue or version number. Each time the document is updated, amended or replaced, a new version number should be used
- the issue date. Include the date when the current version of the document first came into force
- withdrawal date (if applicable)
- review date (if applicable). Documents may require periodic review to ensure the information remains applicable and up to date
- the allocation of controlled copies (i.e. who has a copy of the document).

REFERENCE NUMBER	TITLE	VERSION NUMBER	ISSUE DATE	WITHDRAWAL	REVIEW DATE	ALLOCATED COPIES
P101	Metal Detection Check Procedure	1	1 June 2012	1 January 2013	N/A	J Jones B Brown S Smith
P101	Metal Detection Check Procedure	2	1 January 2013		N/A	J Jones B Brown S Smith
P102	Product Check Weight Procedure	1	1 January 2012		N/A	S Smith G Green

Example of a document list

Identification and authorisation of your documents

The simplest way to identify your document is to include a footer on each page that contains the relevant information. This may include the:

- document reference
- issue or version number
- title of the document
- date of issue
- page number and total number of pages.

REFERENCE: P101		TITLE: METAL DETECTOR CHECK PROCEDURE				
Issue Number: 1		Page: 1 of 5			Issue Date: 1st January 2013	
G001 Acceptance of Raw Materia		lls	Issue 1	F	Page 3 of 4	Issued: 1/1/13

Typical formats for footers

You will need to include a method of authorisation too (e.g. a signature or a stamp that identifies genuine copies of the document). Where these are held electronically, it may be more convenient to label printed copies as uncontrolled copies.

Making changes to your documents

When a document is changed, you will need to make a note of the change and the reason for it. You can do this by:

- keeping a copy of the previous version with the reason for the change written on it, or
- keeping a 'history of amendments' log within each document.

DATE	CHANGES
1 Jan 14	New metal detector purchased which needed to be reflected in this procedure
28 Sept 14	Frequency of checks updated to reflect requirements of a new customer

Example of an amendments log

A new issue or revision always replaces an existing document. You must not have two different issues or revisions of the same document at any time.

You will also need to ensure that any policy or procedure changes are communicated to the relevant staff. This can be done by highlighting the change within the new document or by specific training prior to the issue of the new version. **Replacing your documents** You will need to keep a record of all controlled documents and their allocation. This will mean that whenever a document is updated or replaced, the person responsible can ensure each old copy is returned when the new version is issued. The easiest way to do this is by using a sign-off sheet where staff sign to indicate that they have returned the previous version and collected the new one. **Quick tips** • Ensure a that single, clear procedure operates across the entire food safety and management system. • Ensure the list of documents remains up to date. • Remove old versions of documents from the site.

• Do not have two versions of the same document circulating at the same time. Systematically collect all old

versions for destruction or archiving.

3.3 RECORD COMPLETION AND MAINTENANCE

The site shall maintain genuine records to demonstrate the effective control of product safety, legality and quality.

• Ensure staff are aware of the correct document versions.

Interpretation

Records are documented information that provide permanent evidence about past events – particularly events concerning product safety, quality and legality. Records must therefore be maintained in an appropriate way to ensure they demonstrate control of systems and operations.

CLAUSE	REQUIREMENTS
3.3.1	Records shall be legible, maintained in good condition and retrievable. Any alterations to records shall be authorised and justification for the alteration shall be recorded. Where records are in electronic form these shall also be:
	 stored securely (e.g. with authorised access, control of amendments, or password protected) suitably backed up to prevent loss.
Interpretation	Record completion Records must be legible and genuine; for example, they must be completed at the time of the checks (i.e. not before or after the event) and in an appropriate manner (e.g. using a pen, as pencil could be altered after the event). Records should be appropriately authorised; this may include the initials or signature of the operator or supervisor verifying the records.
	Any alterations to records need to be justified and authorised. A suitable procedure must be in place to manage any mistakes that are made (e.g. neatly crossing through the 'inaccurate' information, noting the reason for the error and giving the initials of the person making the change). Note that the use of correction fluid is not acceptable as this makes the initial information illegible.
	Records must be retrievable when required (e.g. during an audit or during the investigation of a customer complaint), and must therefore be maintained and stored to allow this (e.g. by being appropriately filed by date or reference number and in such a way that they are still legible within the specified storage timeframe). They must be created in such a manner that they accurately transmit the intended information (e.g. they can be read by others and are traceable to the creator of the record via initials or signature).
	Where records are stored electronically, this storage must be secure. The site should ensure that passwords or other mechanisms required to access records are known only by the people who need to use them. When using electronic systems, it may also be useful to assign different access levels; for example, for staff who can view records, and for those who can view records and also add or amend existing data.
	Electronic documents must be suitably backed up to prevent loss. Consideration should be given to testing electronic retrieval systems, and records of these tests should be retained.

CLAUSE **REQUIREMENTS** Records shall be retained for a defined period with consideration given to: 3.3.2 • any legal or customer requirements • the shelf life of the product. This shall take into account, where it is specified on the label, the possibility that shelf life may be extended by the consumer (e.g. by freezing). At a minimum, records shall be retained for the shelf life of the product plus 12 months. Interpretation Record storage The retention time for records must be established by the company, and procedures put in place for appropriate handling, so that records are retained in good condition for this period and are retrievable. Consideration should be given to the potential for degradation during storage (e.g. due to fading ink, degradation of thermal paper or breakdown of electronic media). Records that may be called upon to demonstrate the safety, integrity or legality of the product must be kept for an appropriate period. Examples of appropriate periods for products or ingredients are as follows: • final products – a period not less than the indicated shelf life plus 1 year • ingredients (i.e. where the site sells an ingredient that will be used in the manufacture of a final product) – the shelf life of the final product plus 1 year. Where the final-product shelf life is not reasonably known, records should be kept for 3 years or a period agreed with customers • products of an undefined shelf life (e.g. some wines and alcoholic drinks) – the company should define a reasonable record retention period based on experience of customer usage, time for complaints and any legal precedents. It would be usual for records to be kept for at least 3 years in these situations. Additional retention time may be required by legislation, by customers or because of the nature of the product (e.g., extension beyond the normal shelf life by the inclusion of customer freezing instructions on the product packaging must be observed). As records may be called upon by a customer as part of a legal defence, consideration should be given to the length of time that may pass from production of a product to notification of impending legal action in the country of sale. Some regions have specific legal requirements. FSMA legislation, for example, requires a storage period of a minimum of 2 years for all documents and records relating to the food safety plan, and records must be

3.4 INTERNAL AUDITS

FUNDAMENTAL

The company shall be able to demonstrate that it verifies the effective application of the food safety plan and the implementation of the requirements of the Global Standard for Food Safety.

retrievable within 24 hours, even when stored off-site.

Interpretation

An internal audit is any audit completed by or on behalf of the company rather than by a second or third party. In second-party audits, the company carrying out the audit may have a commercial interest (e.g. a customer audit), while a third-party audit is generally conducted by an independent organisation (e.g. a certification body).

Internal auditing is a key factor in ensuring continued compliance with the requirements of the Standard, and must be regarded by the management of the company as critical to its operation. Internal audits demonstrate whether control systems are working correctly and effectively, and identify areas for improvement. Internal auditing forms part of the verification of systems; this is a crucial step within the control of the HACCP or food safety plan. Therefore this requirement is fundamental.

The scope of the internal audit programme must cover all areas of the food safety and quality system, including all the requirements of the Standard (e.g. implementation of the HACCP or food safety plan, prerequisite programmes and procedures). It must also cover both the systems in place and the work practices.

There shall be a scheduled programme of internal audits. At a minimum, the programme shall include at least four different audit dates spread throughout the year. The frequency at which each activity is audited shall be established in relation to the risks associated with the activity and previous audit performance. All activities shall be covered at least once each year. At a minimum, the scope of the internal audit programme shall include the: HACCP or food safety plan, including the activities to implement it (e.g. supplier approval, corrective actions and verification) prerequisite programmes (e.g. hygiene, pest control) food defence and food fraud prevention plans procedures implemented to achieve the Standard.

Interpretation

Internal audit programme

section of the HACCP or food safety plan.

The primary role of an internal audit programme is to provide an ongoing assessment to ensure that the site is following the written procedures and methods of working defined in its quality system. The scope of internal audits needs to be established and must ensure that all aspects of the food safety and quality system, including the HACCP programme, prerequisite programmes, policies, documentation, hygiene and production, are audited at least annually.

Each internal audit within the programme shall have a defined scope and consider a specific activity or

All the internal audits should not be conducted on a single day, nor should they cover all aspects of the Standard. The Standard states that at least four different audit dates should occur each year. Each date can be used to audit different aspects of the site's systems that have been implemented to comply with the Standard. A once-a-year check against all the requirements may be of value as a gap analysis when preparing for an audit, but is insufficient to cover the full requirements of an internal audit programme as it will not provide the depth of assessment or level of confidence required.

The site must evaluate the risk inherent in each section and determine the frequency of the audits for that specific section or activity accordingly. For example, the site should be aware of the consequences of not complying with its own systems, which could lead to hazards not being identified in a timely manner. Frequency may also be influenced by known issues within the company, best practice or customer requirements. The site must therefore have a schedule or programme of internal audits to ensure that individual sections of the process, documentation or production are scheduled for different, predefined audit dates throughout the year.

Where a site is part of a multi-site company, and the company conducts annual corporate food safety audits, it is acceptable for this annual audit to be incorporated into the internal audit schedule. However, additional internal audits that look at specific parts of the food safety and quality system, and compliance with the Standard, should be scheduled throughout the rest of the year. The frequency of these audits will still be based on risk.

For seasonal production, particularly when the season is very short (e.g. 4 weeks or less), the site must have in place a system for the management of start-up processes. Therefore, internal audits should start before the season commences. For example, the HACCP programme should be reviewed to ensure that it is up to date and appropriate for the forthcoming production; that hygiene and fabrication are correct; and that staff are appropriately trained. The remaining areas of the internal audit programme should be covered throughout the season. Care should be taken to ensure that the requirements that pertain to those seasonal activities are audited appropriately (e.g. that systems are checked when in operation).

The most common way of completing an internal audit is by taking documented procedures and work instructions and comparing them with the actual working practices and records.

The use of an external consultant (e.g. by small sites) is acceptable, providing the internal audit programme is scheduled throughout the year and not in a single block of activity.

BRC Global Standards has produced a guideline to internal auditing which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

Example

													1	
METHOD	FREQUENCY	AUDITOR	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEPT	ОСТ	NOV	DEC
HACCP	-Review process -Check all products & processes included -Review actions from HACCP team meeting	1	x											
Management Review	-Action points from previous meeting -Schedule	1				x								
Approved Suppliers	-Procedures -Supplier register -Monitoring records	2			x									
Raw Material Specifications	-Review records -Complete & up to date documentation e.g. risk assessments -Certificates & test reports	2	x						х					
Traceability	-Forward & Backward traceability exercise & associated paperwork	1				x						x		
Complaints	-Overview of system -Investigations & subsequent actions -Trend analysis	3									x			
Pest Control	-Documentation e.g. contract, procedures, records -Corrective actions	1		х				x				x		
Production	-Records -CCPs -Document control -Changeovers -Calibration	1		x			x			x			x	

Example of an internal audit schedule

A site has a programme of audits where one aspect of the Standard is audited each month. The higher-risk areas, such as CCPs, the hygiene procedures and incoming goods procedures, are audited more frequently. Hygiene is audited monthly, incoming goods quarterly, and other areas identified as lower risk twice a year. To support this activity there is an internal audit team supported by an external consultant who provides summary reports for the senior management team's quarterly review. They list any non-conformities raised, any recurrence of non-conformities, the corrective actions taken, and whether root cause analysis has been deployed. The reports also detail any deviations from the plan (e.g. late internal audits because of an unannounced customer visit) and any measures taken to recover.

As a result, the senior management team have a good awareness of the status of compliance with the requirements of the Standard, any particular areas that require more attention, and areas where excellence is demonstrated. This in turn is publicised across the site to all employees via a communication plan. This plan helps support a good, transparent food safety culture where all employees are kept updated about how the site is performing and each person is aware of their impact on food safety and quality.

3.4.2

Internal audits shall be carried out by appropriately trained, competent auditors. Auditors shall be independent (e.g. not audit their own work).

Interpretation

Auditor training and independence

Good auditing is a thorough, evidence-based assessment of an activity or system, completed by an independent auditor. It should ultimately contribute towards the site's continuous improvement.

Auditing is therefore an acquired skill and auditors need to be trained to ensure they are carrying out this function effectively. Training must include auditing skills as well as relevant technical knowledge of the activity to be audited, such as HACCP or appropriate product technical knowledge. Internal auditors must be able to show via training records (clause 7.1.6) that they have received formal training on internal auditing, via either attendance at an external course or training within the company.

Training should also cover the planning and scheduling of the internal audits, preparing audit reports in the company's agreed format, the correct use of audit techniques (e.g. documentation and process auditing, audit trails and discussions with colleagues) and follow-up of audit findings (see clause 3.4.3).

CLAUSE

REQUIREMENTS

During the BRC Global Standards audit, the auditor may also discuss the process with internal auditors to establish their level of competence. Internal auditors must be independent of the process being audited. This is to ensure that the audit is rigorous and thorough, and that any work needed to make corrections or improvements can be identified by an auditor who is not biased or influenced by working in the area. Internal auditors may not audit their own work or any programmes for which they are immediately responsible. It is not acceptable, for example, for workers on one shift to audit the work of another shift completing the same work, as they are not independent of the operation.

External auditors may be used where internal resources are insufficient, providing the requirements of clause 3.4.1 can be met (i.e. for scheduling audits throughout the year). The training records for external personnel must be available.

Further quidance

What is included in the audit and who should carry it out?

An internal audit should examine the process or activity in detail and will usually include:

- observing how activities are completed
- asking relevant staff how an activity is completed or why it is completed in a specific way
- reviewing procedures and records to confirm whether the activity has been completed and recorded correctly.

Internal auditors must be unbiased, as explained above. It is also easier for an unbiased auditor to identify corrections or improvements as they are not influenced by an in-depth knowledge of that area. However, external auditors can be used if required or preferred.

3.4.3

The internal audit programme shall be fully implemented. Internal audit reports shall identify conformity as well as non-conformity and include objective evidence of the findings.

The results shall be reported to the personnel responsible for the activity audited.

Corrective and preventive actions, and timescales for their implementation, shall be agreed and their completion verified.

Interpretation

Internal audit records and corrective actions

In addition to the actual internal audit, it is important that appropriate reports are completed and that actions are agreed and reviewed. The management review processes (see clause 1.1.4) must ensure that the programme operates effectively and that necessary corrective or preventive actions are appropriately completed. As a result, the internal audit process will often contain a number of steps; for example:

- internal audit completed
- corrective actions agreed
- corrective actions completed and signed off
- completion verified
- root cause analysis used to identify any necessary preventive actions
- preventive actions completed and reviewed
- overall management review completed.

Therefore audit results must be documented, clearly indicating what was audited. Reports must show evidence of conformity as well as non-conformity, with objective supporting evidence (e.g. what documents or actions were observed). Note that tick lists showing that items have been assessed will not normally be accepted as the only form of evidence; information showing how the audited items have fulfilled the requirements, or how they are non-compliant, is required. This is important, as recording conformity is documenting evidence that due diligence is taking place; in other words, that required procedures are being followed, and have been observed by auditors who are independent of the process.

Notes, references or copies of these audits should be kept as evidence of aspects that have been examined, to allow an independent reviewer to reach the same conclusion as the internal auditor. For example, the dates and titles of records that were inspected should be noted in sufficient detail to allow them to be traced; if any records are non-compliant, precise details of the non-compliance should be given. The listing of records reviewed also ensures that a wide range of records are considered (e.g. training records of a variety of staff rather than repeated audits of the same records). Records will also confirm whether anything has changed since the last audit.

The results of audits need to be communicated to the relevant staff, and corrective actions and timescales agreed. This may be achieved via operational or review meetings, or via an update at the end of the audit combined with documentation such as a memo or a copy of the audit report. Responsibility for corrective actions must be documented – for example, by being recorded on the audit record sheet.

Where non-conformities have been identified, effective completion of corrective action must be verified. Good practice is to ensure that a nominated member of staff with the appropriate authority checks that the action has been taken within the agreed timescale, and that this has rectified the problem sufficiently to prevent recurrence. The nominated staff member should not be the person responsible for completion of the actions; ideally this should be the original auditor.

Root cause analysis tools should be used to identify appropriate preventive actions; i.e. actions that will prevent a recurrence of the non-conformity. Good practice with preventive action is to consider not just the area or activity where the non-conformity occurred, but also whether the non-conformity could occur elsewhere in the site or its procedures (see the example below).

Full records of all internal audits and the results, including conformities and non-conformities and verification of corrective and preventive actions, must be kept for a defined period, typically 2 years.

AREA REQUIREMENT: Control of	of Non-Conforming Product	DATE: 14 February 14 AUDITOR: A Checker	
BRC REQUIREMENT	SITE POLICY	EVIDENCE	COMPLIES

An example of a completed audit report

BRC Global Standards has produced a guideline to preventive action and root cause analysis which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

Example

During an internal audit, a leaky roof is identified. Corrective action is completed immediately using a temporary repair. However, a leak could occur elsewhere on the site. Preventive action should consider not only when and how a permanent fix to the current leak will be completed, but also relevant actions to prevent the same non-conformity occurring elsewhere on site. For example, the current programmes of building fabrication inspections (clause 3.4.4) and maintenance condition monitoring (clause 4.7.1) could be reviewed to ensure these are appropriate.

CLAUSE **REQUIREMENTS** In addition to the internal audit programme, there shall be a separate programme of documented 3.4.4 inspections to ensure that the factory environment and processing equipment are maintained in a suitable condition for food production. At a minimum, these inspections shall include: hygiene inspections to assess cleaning and housekeeping performance • fabrication inspections to identify risks to the product from the building or equipment. The frequency of these inspections shall be based on risk but will be no less than once per month in open product areas. Interpretation **Documented inspections** The Standard requires a programme of documented inspections to ensure that the factory environment and processing equipment are maintained in a suitable condition. These inspections are different from the internal audit programme specified in clauses 3.4.1 to 3.4.3, which examines practices against documented procedures. Audits are an in-depth challenge to the systems and procedures that a site has put in place to manage hazards, to confirm that the site is effectively mitigating identified risks. A documented inspection, however, is a simpler approach to assessing the conditions present, so an entirely separate inspection plan should be in place. These hygiene- and fabrication-based inspections assess standards of cleaning, equipment, building fabrication and personal hygiene to ensure that high standards are maintained and that a safe, hygienic production environment is in place. For example, completion of an equipment inspection can identify and control potential foreign bodies (e.g., from worn or damaged equipment) before they have the opportunity to

The frequency of the inspections should be based on risk. For open product areas, inspections need to be at least monthly, whereas inspections in high-care and high-risk areas are likely to be more frequent (e.g. daily or weekly); seasonal products or activities should be included where appropriate. Line start-up checks, which may occur daily or at shift changes in many operations, can form part of this inspection programme.

The individuals responsible for completing these inspections should be suitably trained for the systems they are checking. The absolute requirements for independence identified in clause 3.4.2 do not always apply to these inspections; for example, it would be acceptable for line start-up checks to be carried out by line supervisors or managers. External agencies may be used to carry out inspections.

It is important that issues identified at the inspections are corrected as soon as possible so that product risk is minimised. The records of inspections and corrective actions must be retained.

Inspection records can provide useful information to identify trends and drive improvements (e.g. through the use of scored inspection results).

Quick tips

- Schedule internal audits for the whole year based on risk assessment.
- Ensure all areas of the food safety and quality management system are included.
- Ensure there are sufficient trained internal auditors.
- Do not assume auditors can just squeeze an audit in. Sufficient time must be made available.
- Set a format or template to ensure consistent records are kept.
- Ensure auditors are independent of the areas being audited.
- Do not try to complete all the audits at one time (e.g. all on one day or within 1 week). Use a risk-based schedule.

BRC Global Standards has published a best-practice guideline to internal audits that can be obtained from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

contaminate a product.

3.5 SUPPLIER AND RAW MATERIAL APPROVAL AND PERFORMANCE MONITORING

3.5.1 MANAGEMENT OF SUPPLIERS OF RAW MATERIALS AND PACKAGING

FUNDAMENTAL

The company shall have an effective supplier approval and monitoring system to ensure that any potential risks from raw materials (including primary packaging) to the safety, authenticity, legality and quality of the final product are understood and managed.

Interpretation

All materials brought onto the site to become part of the final product (including product packaging) must be sourced through approved suppliers and monitored. This approval process and programme for monitoring raw materials will consider the potential risk the material represents (in terms of safety, authenticity, legality and quality).

The system must consist of an initial approval process and an ongoing monitoring process.

The risk assessment process should help to focus increased attention on the raw materials or suppliers that present a greater risk.

CLAUSE	REQUIREMENTS
3.5.1.1	The company shall undertake a documented risk assessment of each raw material or group of raw materials including primary packaging to identify potential risks to product safety, legality and quality. This shall take into account the potential for:
	 allergen contamination foreign-body risks microbiological contamination chemical contamination variety or species cross-contamination substitution or fraud (see clause 5.4.2) any risks associated with raw materials which are subject to legislative control.
	Consideration shall also be given to the significance of a raw material to the quality of the final product.
	The risk assessment shall form the basis for the raw material acceptance and testing procedure and for the processes adopted for supplier approval and monitoring.
	The risk assessment for a raw material shall be updated:
	 when there is a change in a raw material, the processing of a raw material, or the supplier of a raw material if a new risk emerges following a product recall or withdrawal, where a specific raw material has been implicated at least every 3 years.

Interpretation

Raw material risk assessment

All proposed ingredients and packaging must be subjected to a documented assessment of their inherent risk. This may form part of the HACCP or food safety plan; however, as this is an important starting point for the production of safe food, it needs to be detailed and will be specifically assessed by the auditor. The assessment may be of individual products or, where a number of raw materials share the same characteristics and likely risks, these may be grouped together. When grouping materials, each should still be considered separately to ensure that it does not have different risk factors from the rest of the group. Risk, and therefore the opportunity to group ingredients or not, may vary between factories and processes because of the different overall effect on quality. For example, in a bakery, all dried fruit may be considered to be of similar risk, but where flour is a critical ingredient, it may be necessary to consider each type of flour separately (e.g. white, granary or wholemeal); however, other non-bakery sites may group all the types of flour together.

CLAUSE

REQUIREMENTS

Regarding the chemical contamination risk stated in the requirement above, examples could be contaminants that occur naturally in the environment, those that migrate from packaging materials, or artificial additions in the supply chain (such as pesticides or veterinary medicines).

When considering the risk of non-compliance with legal requirements specific to the product line (e.g. banned substances), it is important to remember that legislative requirements in the country of raw material production may be different from those of the country where the site is located. This is particularly important when importing ingredients. For example, the company should consider:

- known hazards associated with the ingredient provided or components of it (e.g. aflatoxins in nuts and cereals, histamine in fish, pesticide residues in products of plant origin, Salmonella in dried foods such as milk powder, and Listeria in chilled foods). Access to reference information and an awareness of emerging food issues are essential to ensure all known risks are assessed (clause 1.1.8)
- use of the ingredient (e.g. an ingredient added following the final kill step may present a different risk from an ingredient added at the beginning of a process)
- spread of ingredient in the company/final products
- nature of the supplier
- historical evidence of the supplier and raw material
- geographic origins (products from particular origins may carry a greater risk due to environmental conditions, because of more relaxed local legal requirements or a less developed food safety culture)
- methods of manufacture (e.g. if a site is using pineapple as an ingredient, the risk will depend on whether fresh or canned pineapple is used)
- significance of the ingredient to the final product (e.g. some 'safe' ingredients, such as flour in breadmaking, may be fundamental to the performance of the product and therefore require higher levels of control to ensure consistent quality)
- customer or legislative requirements (e.g. suppliers may be specified by customers, but this does not negate the need for risk assessment)
- the potential for fraudulent activity in the supply chain; for example, undeclared additions, dilution or substitution of the raw material or a component of it. (This part of the risk assessment may be completed as part of the vulnerability assessment in clause 5.4.2.)

Additional focus must be placed on raw materials where claims are being made about the final product (e.g. 'organic' or 'suitable for allergy sufferers') or where there is a microbiological risk from components added after heat treatment. Suppliers and their control systems must be assessed robustly to ensure compliance with the requirements.

Sites should also consider the primary packaging materials used as they too are raw materials. There is potential for packaging materials to pose a problem, whether because of contamination, malicious intervention or the use of inappropriate materials.

Where different departments are involved in the process (e.g. head office or different sections of the site technical team), there needs to be a linked process to demonstrate the responsibilities of each team and how these work together to operate the system. The outcome of this activity must also be considered when assessing the requirements for supplier approval and for monitoring and acceptance procedures (clauses 3.5.1.2 and 3.5.2).

Risk assessments must be up to date and the site should therefore review the assessment whenever there is a significant change (e.g. new suppliers, new countries of origin or an emerging risk) or where an incident (e.g. a product withdrawal) is related to a specific raw material. At a minimum risk assessments must be reviewed every 3 years.

CLAUSE **REQUIREMENTS** The company shall have a documented supplier approval procedure to ensure that all suppliers of raw 3.5.1.2 materials, including primary packaging, effectively manage risks to raw material quality and safety and are operating effective traceability processes. The approval procedure shall be based on risk and include either one or a combination of: a valid certification to the applicable BRC Global Standard or GFSI-benchmarked standard. The scope of the certification shall include the raw materials purchased • supplier audits, with a scope to include product safety, traceability, HACCP review and good manufacturing practices, undertaken by an experienced and demonstrably competent product safety auditor. Where the supplier audit is completed by a second or third party, the company shall be able to: demonstrate the competency of the auditor confirm that the scope of the audit includes product safety, traceability, HACCP review and good manufacturing practices obtain and review a copy of the full audit report or • where a valid risk-based justification is provided and the supplier is assessed as low risk only, a completed supplier questionnaire may be used for initial approval. The questionnaire shall have a scope that includes product safety, traceability, HACCP review and good manufacturing practices, and it shall

Interpretation

Documented supplier approval and monitoring system

have been reviewed and verified by a demonstrably competent person.

All suppliers must be evaluated for their ability to meet the specifications of the materials (ingredients and primary packaging) they are supplying and requirements for safety, quality and legality.

The company must document its procedure for supplier approval and monitoring. This needs to include the methods of approval, frequency of monitoring, responsibilities and how the process will be managed.

The acceptable methods of supplier approval will depend on the raw material and the risks associated with it (e.g. the output of clause 3.5.1.1); they will include one or more of the following activities:

- certification to the relevant BRC Global Standards scheme, such as the Global Standards for Food Safety;
 Packaging and Packaging Materials; Storage and Distribution; Agents and Brokers; or another of the
 GFSI-benchmarked schemes. The site must confirm the validity of the certification. This will include:
 - confirmation of the certification status (e.g. this can be confirmed on an independent database; for BRC Global Standards it can be confirmed at www.brcdirectory.com). Photocopies of certificates are not recommended and on their own are not considered suitable validation of certification status.
 During the BRC Global Standards audit the site may be asked to demonstrate its validation process
 - confirmation that the certification remains up to date (e.g. by receiving confirmation of successful completion of the recertification processes or by recording certificate expiry dates and completing checks for ongoing certification)
 - ensuring that the raw materials are within the scope of the certification.

A successful site audit covers at a minimum product safety, traceability, HACCP and good manufacturing processes. This audit must be completed by an appropriately experienced and competent auditor (i.e. someone who has completed training in auditing techniques, has experience of auditing, and has knowledge of the product, ingredient or processes being audited). Non-conformities should be addressed (e.g. in an agreed action plan with timescales) unless they are critical to product safety or legality, in which case supply should not be permitted until the non-conformities have been satisfactorily addressed. If the raw material supplier is independently audited to another standard that is not GFSI-benchmarked, this may be acceptable as an alternative to the site completing its own audit of the supplier providing that:

- the scope of the audit meets the requirements of the Standard (i.e. at a minimum product safety, traceability, HACCP review and good manufacturing practices)
- the site has a copy of the full audit report (not just a certificate)
- the supplier can demonstrate the competence of the auditor.

Where risk assessment (completed as part of this clause) indicates that a supplier is low-risk (e.g. due to history of trading with the site or the nature of the raw materials traded) the completion of a supplier questionnaire with a focus on food safety and quality may be sufficient. If a supplier questionnaire is the only mechanism used to assess a supplier (i.e. there are no additional activities such as supplier audits) then it is important that the questionnaire (and replies from the ingredient supplier) contains all the relevant information to allow the site to confidently make a decision on approval.

The auditor will expect to see, and will challenge, risk assessments.

Approval and the associated risk assessments must be up to date. The site should therefore consider reviewing the assessment whenever there is a significant change (e.g. new suppliers, new countries of origin or new materials).

3.5.1.3

There shall be a documented process for ongoing supplier performance review, based on risk and defined performance criteria. The process shall be fully implemented.

Where approval is based on questionnaires, these shall be reissued at least every 3 years and suppliers shall be required to notify the site of any significant changes in the interim, including any change in certification status.

Records of the review shall be kept.

Interpretation

Ongoing monitoring

Although it is important to know how and why suppliers are approved, it is also vital to ensure that ongoing approval is justified. The site is free to determine how it confers continuing approval on its suppliers, but it is important that the site uses a risk-based approach.

The defined performance criteria can be determined by the site and should depend on the supplier's performance. As a quide, this may include:

- the risks associated with the raw material or supplier
- incidences of contamination or non-conforming raw materials
- quality of material supplied.

The frequency of ongoing approval is also important, and this is left to the site to determine. However, where approval is based on supplier questionnaires, these must be reissued at least every 3 years.

The site must be able to demonstrate to an auditor that the monitoring and ongoing review it uses is appropriate, justified and risk-based.

3.5.1.4

The site shall have an up-to-date list or database of approved suppliers. This may be on paper (hard copy) or it may be controlled on an electronic system.

The list or relevant components of the database shall be readily available to the relevant staff (e.g. at goods receipt).

Interpretation

Approved suppliers list

The company must also maintain an up-to-date list of approved suppliers based on the outcome of the supplier approval process. This list can either be in hard copy (i.e. paper) or electronic format (such as an approval database). It is expected that all purchased raw materials (including packaging) will be from the suppliers on the list unless it is an emergency purchase covered by clause 3.5.1.7.

The auditor may refer to the list to facilitate the effective sampling of supplier approval records.

The list (or relevant sections of it) should be available where goods are taken in, and be accessible to anyone who needs it at the points at which it should be used. This is likely to include purchasing where this activity is carried out at the site (i.e. not at a corporate facility).

CLAUSE	REQUIREMENTS
3.5.1.5	Where raw materials (including primary packaging) are purchased from companies that are not the manufacturer, packer or consolidator (e.g. purchased from an agent, broker or wholesaler), the site shall know the identity of the last manufacturer or packer, or for bulk commodity products the consolidation place of the raw material.
	Information to enable the approval of the manufacturer, packer or consolidator, as in clauses 3.5.1.1 and 3.5.1.2, shall be obtained from the agent/broker or directly from the supplier, unless the agent/broker is themselves certificated to a BRC Global Standard (e.g. BRC Global Standard for Agents and Brokers) or a standard benchmarked by GFSI.
Interpretation	Purchasing from agents and brokers Potential product safety risks need to be understood for all raw materials, including those that have been purchased through an agent or broker (see glossary, Appendix 2).
	The purpose of this clause is to ensure that, where a site has purchased a raw material from an agent or broker, or a wholesaler (i.e. not the manufacturer, packer or consolidator), the site has sufficient information to ensure traceability and to enable the approval of the last processor of the raw material, the last point of packing or the consolidation place for bulk commodity products, as described in clause 3.5.1.2. This information can be provided directly by the manufacturer, processor, packer or consolidator or alternatively through the agent or broker.
	Primary packaging materials are also included in this clause. Packaging is vital to product integrity in the packing environment and further through the supply chain, therefore it is vital that its integrity is assured. Primary packaging is the most crucial, as it directly contacts the product. It is defined in the Standard as:
	'The packaging that constitutes the unit of sale to the consumer or customer (e.g. bottle, closure and label of a retail pack or a raw material bulk container).'
	Where the agent or broker is certificated to the BRC Global Standard for Agents and Brokers, the wholesale module of the BRC Global Standard for Storage and Distribution, or the relevant traded products/goods scope (e.g. Food Safety Standard section 9, or Packaging Materials module), the requirement to approve the processor, packer or consolidator is not applicable, as the requirements of these Standards ensure that effective systems for supplier approval and traceability are in place. However, the site will still be expected to know the identity of the processor, packer or consolidator.
3.5.1.6	The company shall ensure that its suppliers of raw materials (including primary packaging) have an effective traceability system. Where a supplier has been approved based on a questionnaire instead of certification or audit, verification of the supplier's traceability system shall be carried out on first approval and then at least every 3 years. This may be achieved by a traceability test.
	Where a raw material is received directly from a farm or fish farm, further verification of the farm's traceability system is not mandatory.
Interpretation	Supply chain traceability It is important for the integrity of products that appropriate traceability systems operate throughout the supply chain. Therefore sites must ensure that their raw material suppliers (including primary packaging suppliers) have suitable traceability systems in operation. This assurance can be obtained from certification, auditing or by directly testing traceability. Examples of acceptable traceability include:
	 the raw material supplier is certificated to a GFSI-benchmarked standard. Assessment of traceability systems forms part of these audits and therefore no additional action is required to comply with the requirements of this clause; however, a communication mechanism should be in place, such that if the raw material supplier were no longer certificated, the site would be made aware of this change the raw material supplier is audited by the site and the audit includes an assessment of the traceability systems. This would comply with the requirement as traceability has been assessed. The audit should be repeated at least every 3 years verification of a supplier's traceability system where approval has been based solely on a questionnaire with no additional testing (unless the raw material is a primary agricultural product purchased directly

from a farm or fishery, where additional testing of the traceability systems is not mandatory). This

verification could include, for example:

CLAUSE

REQUIREMENTS

- a test of the raw material supplier's traceability. For example, as part of the site's traceability test
 (see clause 3.9.3), a relevant ingredient is highlighted. The ingredient and batch details are forwarded
 to the supplier to enable them to complete the traceability test for the specific batch of raw materials
 and send the relevant records back to the site
- a worked example from the raw material supplier, which clearly explains the traceability process
- a detailed description of the traceability system provided by the raw material supplier.

Information received during the traceability verification should be incorporated into the supplier approval process (clause 3.5.1.2).

Traceability verification is a requirement for each raw material supplier. Therefore any traceability test (because the supplier approval is based solely on a questionnaire) should be designed to test the raw material supplier's systems and not to trace every single material they produce. Where a site purchases multiple ingredients from the same raw material supplier, it is not a requirement to complete a traceability test for every single ingredient purchased; only to complete the traceability test for each supplier from which ingredients are purchased.

The frequency of the traceability verification should link to the supplier approval programme; that is, the traceability is verified on first approval of the supplier, and then at least every 3 years. It is good practice to phase these verifications over the 3-year period rather than trying to complete them for all sites at once.

During the BRC Global Standard audit the auditor will not undertake a test of raw material suppliers' traceability systems but they will review the site's processes and the information received from its raw material suppliers.

Issues arise with raw materials from time to time so it is beneficial to consider the monitoring of any materials that may need further transparency within the supply chain. This ensures that the site is proactive, not reactive, potentially mitigating the risk of future concerns about raw materials.

3.5.1.7

The procedures shall define how exceptions to the supplier approval processes in clause 3.5.1.2 are handled (e.g. where raw material suppliers are prescribed by a customer) or where information for effective supplier approval is not available (e.g. bulk agricultural commodity products) and instead product testing is used to verify product quality and safety.

When a site produces customer-branded product, the customer shall be made aware of the relevant exceptions.

Interpretation

Exception procedure

In cases where emergency supplies (e.g. where an established supplier is unable to fulfil an order), bulk commodity purchases or purchases from a supplier prescribed by a customer make it impossible to operate the approval processes in clause 3.5.1.2, the site must have a procedure detailing how these exceptions are to be handled. The process will include an assessment of the risk of the purchase and the completion of appropriate checks or tests to mitigate any risk. For example, this may include:

- 100% inspection of the product
- certificates of analysis
- increased microbiological sampling
- review of a third-party audit report
- a formally agreed specification
- confirmation of compliance with customer codes of practice.

Where raw materials are obtained from a customer-designated supplier (e.g. packaging or when contract packing), the site must ensure that information is obtained about the product and supplier so that potential risks to other products are assessed and controlled. Where the materials are used to produce a customer-branded product, the exceptions must be communicated to the customer.

3.5.2 RAW MATERIAL AND PACKAGING ACCEPTANCE, MONITORING AND MANAGEMENT PROCEDURES

Controls on the acceptance of raw materials (including primary packaging) shall ensure that these do not compromise the safety, legality or quality of products and where appropriate any claims of authenticity.

Interpretation

Verification procedures need to be in place to demonstrate that materials (including ingredients and primary packaging) from approved suppliers meet agreed specifications and do not compromise the safety, legality, quality or authenticity of products.

CLAUSE	REQUIREMENTS
3.5.2.1	The company shall have a procedure for the acceptance of raw materials and primary packaging on receipt based upon the risk assessment (clause 3.5.1.1). Acceptance of raw materials (including primary packaging) and their release for use shall be based on either one or a combination of:
	 product sampling and testing visual inspection on receipt certificates of analysis (specific to the consignment) certificates of conformance.
	A list of raw materials (including primary packaging) and the requirements to be met for acceptance shall be available. The parameters for acceptance and frequency of testing shall be clearly defined, implemented and reviewed.

Interpretation

Acceptance of raw materials

The acceptance or goods-in system must include a documented procedure which requires checks to be completed and any non-conformities recorded. The procedure should document who is authorised to accept conforming materials and reject non-conforming batches, and the action to be taken.

In addition to checking the accuracy of the order to ensure that the correct materials, grades and quantities have been delivered, specific checks will be based on the risk assessment (clause 3.5.1.1) and the specification (clauses 3.6.1 to 3.6.4), and will include one or more of the following:

- specific raw material testing to ensure conformance with the specification before acceptance or use
- temperature checks (particularly for chilled or frozen materials) and storage instructions (refrigeration, freezing, or segregation for allergens)
- visual inspection (e.g. for cleanliness, damaged packaging and spills, infestation, pallet condition)
- the accuracy of printed packaging and labels
- sampling (where required) which should include the timing, method and responsibility for completion, as well as retention of samples
- management of non-conforming product (this should also include ingredients that must be kept 'on hold' pending further testing or investigation)
- certificates of analysis specific to the consignment (i.e. specific to batch, date or lot codes included in the delivery)
- certificates of conformance specific to the consignment
- all legal requirements; for example, EU legislation includes labelling requirements for foods and some additional specific requirements for certain food types (e.g. country-of-origin labelling of meat).

Goods-in acceptance procedures must be fully implemented and therefore it is expected that the procedures and any testing or sampling requirements will be available in the goods receipt area. This may, for example, take the form of a product acceptance matrix identifying each material's acceptance criteria and, where applicable, the sampling frequency.

Records of the raw material checks for each batch of material must be maintained. They are likely to be assessed as part of the traceability challenge completed during the audit (see Part III, section 2.2 of the Standard).

CLAUSE

REQUIREMENTS

Further guidance

Assessing the level of checks needed

Although some checks will be applicable to all deliveries (e.g. the state of the delivery vehicle), the risk assessment (completed as part of clause 3.5.1.1) should be used to establish the level of control required for each ingredient, with higher-risk ingredients needing more checks before they are accepted. For example, you will need to assess whether a certificate of conformity is sufficient or whether a more rigorous assessment is needed, such as independent certification status, a certificate of analysis or product testing.

Where a certificate or other documentation is required, it is important that the critical data is clearly defined and checked; i.e. that the specific tests and acceptable limits are documented. For example, if the risk assessment highlights a potential microbiological risk, then the certificate of analysis must show the relevant organism(s). But if the risk is an allergen, there will need to be an allergen result. On receipt of a batch of ingredients the certificate will be checked for the relevant tests, as well as ensuring that the value is within defined critical limits.

Where a control is applied to a percentage of batches (e.g. a monthly quality assurance test rather than one at every delivery), it is particularly important that mechanisms are in place to ensure this works effectively. It is much easier to miss a test if it is not applied to every delivery.

Example

SUPPLIER'S NAME	SUPPLIER'S NAME PRODUCT(S) SUPPLIED		FREQUENCY OF CHECKS	ACCEPTANCE CRITERIA	
Full Name of Approved Supplier	supplier is approved to the specific ingredient		Frequency with which the activity must be completed	Critical limit must be clearly documented	
A Browns	Unsalted Butter	CoC Temperature control of vehicles/delivery	All deliveries	CoC to confirm compliance with specification (BrownsButter V1) Temperature < 4°C	
A BIOWIIS	Salted Butter	CoC Temperature control of vehicles/delivery	All deliveries	CoC to confirm compliance with specification (BrownsButter V2) Temperature < 4°C	
	Gluten Free Rice Flour 123 Grade X	CoA for Gluten Content Requires QA testing & release	All deliveries	CoA: Gluten <10mg/kg TQA: Test Gluten <10mg/	
A Smiths	Maize Flour (<500micron)	• CoC • Requires QA testing	CoC: All deliveries QA: Quarterly	CoC to confirm compliance with specification (SmithsMaize V1). QA: Test Gluten <10mg/kg	

An example of a delivery checklist of raw materials from approved suppliers

In addition to the tests listed above all deliveries will be checked for:

- Cleanliness of delivery vehicle no spillages permitted, no odours likely to taint materials
- Integrity of packaging damaged packs to be rejected
- Pest control no evidence of pest ingress.

Further guidance

Maintaining your records

Records of each delivery and the checks that have been carried out must be carefully maintained. Typically the records will indicate:

- date and time of delivery
- identification of the raw material and quantity delivered
- list of checks completed:
 - transport status (e.g. visual inspection of hygiene of vehicle)
 - raw material packaging (e.g. damage, spillages and packaging integrity)
 - accuracy and acceptability of product delivery (e.g. the correct ingredient from an approved supplier including the quantity delivered, grade or quality of the ingredient, date or lot coding and whether the shelf life is acceptable)
 - paperwork associated with the batch of ingredients (e.g. is the appropriate certificate of analysis available for this specific batch? Are the relevant tests listed and are the values within the defined acceptance limits?)
 - additional or product-specific checks completed on receipt (e.g. product temperature)
- requirements for further testing
- identification of the staff completing the checks.

Example

	i							
DATE/ TIME	SUPPLIER	INGREDIENT	CODING	BBE/UB	CHECKS REQUIRED	RESULTS	ACCEPTABLE/ COMMENTS	ВУ
When it arrived	Who is it from? Are they on the approved supplier list?	What it is? Include detail (e.g. grade)	Batch or Lot Codes & any traceability information	BBE or UB for stock rotation	Required checks for the ingredient	Results of the checks	If acceptable release into production/ store. Ensure any out of specification results and subsequent actions are recorded. If on-hold waiting QA or tests results note this	Record who did these activities
24/1/13 9am	A Browns	Unsalted Butter	ABB1301	1/3/13	Vehicle Pest Packaging CoC Temperature	OK OK OK CoC OK 3°C	All tests acceptable. Chill store	MN
24/1/13 3.30pm	A Smiths	Gluten Free Rice Flour 123 Grade X	123X_01_13	31/12/13	Vehicle Pest Packaging CoA Gluten	OK OK OK CoA OK	On-hold awaiting gluten test results	MN

In the latter example (Gluten Free Rice Flour) the QA department need to update the record when the results become available and ensure ingredient is either released into production (acceptable results) or disposed of (unacceptable results)

e.g. Gluten results <10ppm received 31/1/13 signed QA.

An example of a goods-in acceptance sheet

CLAUSE	REQUIREMENTS
Further guidance	Managing receipt of materials Following the goods receipt checks the site will need to take appropriate action to manage the ingredient. Typically this will be one of the following:
	 Accept the batch of ingredient, enter it into the site's systems for traceability and stock control and move it into the appropriate storage area until it is required for production. It is important that temperature- sensitive ingredients are moved in a timely fashion and not left sitting in goods receipt for a prolonged period.
	 The batch of raw material is put 'on hold' awaiting further paperwork from the supplier, product testing or quality assurance release. The site will need to have a clear policy on labelling and taking action to ensure materials that are on hold are not accidentally used. The site rejects the batch of raw material as it does not meet the required standards. The appropriate site
	representative will need to contact the raw material supplier and agree the next steps.
	Again, a clear procedure is needed to ensure the ingredient is either segregated and labelled to ensure that it is not accidentally used, or is not off-loaded from the delivery vehicle.
3.5.2.2	Procedures shall be in place to ensure that approved changes to raw materials (including primary packaging) are communicated to goods receipt personnel and that only the correct version of the raw material is accepted. For example, when labels or printed packaging have been amended, only the correct version should be accepted and released into production.
Interpretation	Communicating changes to goods receipt It is common for raw materials, including primary packaging, to change throughout the life of a product because of the nature of supply or changes to the product. When this occurs, this requirement is designed to ensure that changes are communicated throughout the organisation so that only the relevant materials are shipped into the site.
	This requirement is intended to eliminate the risk of accidental inclusion of out-of-date raw materials or packaging in the product by ensuring that only the correct materials are accepted onto the site.
	This is particularly pertinent with packaging materials where print has been changed to reflect changed raw materials and, potentially, allergens. Good practice would ensure that approved packaging samples are supplied to the goods-in team with the relevant part codes that can be visually checked by goods receipt staff.
Further guidance	The importance of good communication Effective communication systems are vital to ensure that relevant information flows effectively between the teams involved in raw material management. For example:
	 the goods-in team need to know the quantities of material ordered the quality assurance department need to know when ingredients that require testing or releasing into production are received the technical, quality assurance and buying teams need to know if a non-conforming product has been received.
	This clause also requires changes to raw materials to be communicated to the goods receipt team in a timely manner to ensure that only correct up-to-date materials are accepted.
3.5.2.3	Where the site is in receipt of live animals, there shall be an inspection by a suitably competent individual at lairage and post mortem to ensure that the animals are fit for human consumption.

CLAUSE **REQUIREMENTS** Interpretation Live animal inspection This requirement relates only to sites that are in receipt of live animals, such as slaughterhouses. The purpose of the inspection is to ensure that the animals are not diseased and are fit for slaughter for human consumption. The inspection must be carried out both before and after slaughter. It should also identify any live animals that may present an increased risk of cross-contamination in the plant; for example, excessively dirty or Salmonella-positive flocks. Such animals require extra actions, such as cleaning or slaughter at the end of production, to ensure that cross-contamination of unaffected animals or products does not occur. In most countries official veterinary inspections occur before and after slaughter. This fulfils the primary requirements of the clause. In the absence of an official veterinary inspection the checks must be carried out by site staff who understand the signs of disease that present a risk to human consumption and any legislative requirements, and they must have the authority to reject animals or organs. Where an animal is found to be unfit for human consumption, the site would be expected to have procedures in place for the segregation of unfit meat or animals to prevent them from entering the human food chain. Records should be kept of the inspections and numbers of animals rejected and the reasons. **Quick tips** • Ensure relevant staff are trained in the correct procedures. Ensure that documents (e.g. approved supplier lists or copies of orders) are readily available in the goods receipt area.

3.5.3 MANAGEMENT OF SUPPLIERS OF SERVICES

The company shall be able to demonstrate that where services are outsourced, the service is appropriate and any risks presented to food safety, legality and quality have been evaluated to ensure effective controls are in place.

and store them appropriately within the defined timescales.

Do not leave temperature-sensitive ingredients at goods receipt for a prolonged period – process them

• Ensure there are effective communication processes between the relevant departments.

• Have a clear on-hold or reject system in force.

Interpretation

Supplier approval must include the suppliers of services that could potentially affect product safety, legality or quality; for example, the use of agencies to provide temporary staff, laundries, maintenance of equipment (e.g. refrigeration units), waste removal or transport.

CLAUSE	REQUIREMENTS
3.5.3.1	There shall be a procedure for the approval and monitoring of suppliers of services. Such services shall include, as appropriate:
	 pest control laundry services contracted cleaning contracted servicing and maintenance of equipment transport and distribution off-site storage of ingredients, packaging or products off-site packing of products laboratory testing catering services waste management.
	This approval and monitoring process shall be risk-based and take into consideration:
	 risk to the safety and quality of products compliance with any specific legal requirements potential risks to the security of the product (i.e. risks identified in the vulnerability and food defence assessments).

Interpretation

Approval and monitoring of service providers

The site must document its procedure for the risk-based approval and monitoring of suppliers of services to ensure that these suppliers are competent and capable of providing the service to the required level.

Approval may include a combination of the following:

- membership of a recognised trade association which specialises in the service provided (e.g. pest control)
- historical experience with the supplier
- legal registration (e.g. waste licences)
- third-party certification to a recognised standard (e.g. the BRC Global Standard for Storage and Distribution)
- evidence of training and competence in food safety.

It may be appropriate to undertake audits or questionnaires where a service is performed off-site and may present a food safety risk (e.g. laundry services for high-risk/high-care clothing).

The performance of the supplier should be formally reviewed at a frequency appropriate to the service. For example, an outsourced cleaning service would be assessed as part of the internal audit process (section 3.4) and records maintained of feedback on performance to the cleaning company. Other services, such as pest control or laundry, may be reviewed with the supplier on a 6-monthly or annual basis and a record kept of the review (e.g. minutes of the meeting).

3.5.3.2

Contracts or formal agreements shall exist with the suppliers of services that clearly define service expectations and ensure that the potential food safety risks associated with the service have been addressed.

Interpretation

Contracts with service providers

Contracts or formal agreements must be in place for the service providers detailed in clause 3.5.3.1 to ensure the correct level of service is provided. Service providers who will be on site will need to receive appropriate training to ensure they complete their activities in a way that will not negatively impact on the safety, quality or legality of products being manufactured (clause 7.1.1).

3.5.4 MANAGEMENT OF OUTSOURCED PROCESSING

Where any process step in the manufacture of a product is outsourced to a third party or undertaken at another site, this shall be managed to ensure it does not compromise the safety, legality, quality or authenticity of the product.

Interpretation

This section applies to products that are included within the scope of a site's certification but which have a process step that is outsourced to another company or site. This includes products or intermediates that are partially processed at another location (even a site within the same organisation or group) before being returned to the site for further work or packing. This typically happens when there is a need for specialist equipment (e.g. agglomeration of powders or freeze drying); alternatively the product may be sent to a region with a lower-cost economy for a very labour-intensive part of the process.

The scope of the report and any certificate will reflect the activities undertaken only at the site where the audit was undertaken. Products that are entirely manufactured at a separate site (i.e. where co-manufacturing occurs), rather than just part of the manufacturing process being outsourced, are not covered by these requirements. Here the expectation is that each individual site will be certificated and traceability coding should be able to identify at which site the product was manufactured.

CLAUSE	REQUIREMENTS
3.5.4.1	The company shall be able to demonstrate that, where part of the production process or any part of the final packing is outsourced and undertaken off-site, this has been declared to the brand owner and, where required, approval granted.

CLAUSE **REQUIREMENTS** Interpretation **Brand owner approval** Customers (e.g. brand owners) must be notified of any intention to outsource part of the production process. (Some brand owners require the opportunity to formally approve or reject this type of outsourcing.) For example, if this is clearly detailed on the approved product specification, then it would demonstrate that the customer has agreed the process. This requirement is not limited to retail-branded products or to certain markets but applies to any product manufactured on behalf of a customer. The company shall ensure that outsourced processors are approved and monitored, to ensure that they 3.5.4.2 effectively manage risks to product safety and quality and are operating effective traceability processes. The approval and monitoring procedure shall be based on risk and include either one or a combination of: • a valid certification to the applicable BRC Global Standard or GFSI-benchmarked standard. The scope of the certification shall include the raw materials purchased

or

- supplier audits, with a scope to include product safety, traceability, HACCP review and good manufacturing practices, undertaken by an experienced and demonstrably competent product safety auditor. Where this supplier audit is completed by a second or third party, the company shall be able to:
 - demonstrate the competency of the auditor
 - confirm that the scope of the audit includes product safety, traceability, HACCP review and good manufacturing practices
 - obtain and review a copy of the full audit report.

There shall be a documented process for ongoing supplier performance review, based on risk and defined performance criteria. The process shall be fully implemented. Records of the review shall be kept.

Interpretation

Outsourced processor approval

The company must document its procedure for approval and monitoring of outsourced processors. This needs to include the methods of approval, frequency of monitoring, responsibilities and how the process will be managed.

The acceptable methods of approval will depend on the nature of the activity performed and its associated risks, and will include one or more of the following:

- certification to the relevant BRC Global Standards scheme or another of the GFSI-benchmarked schemes. The site must confirm the validity of the certification. This will include:
 - confirmation of the certification status (e.g. this can be confirmed on an independent database; for BRC Global Standards it can be confirmed at www.brcdirectory.com). Photocopies of certificates are not recommended and on their own are not considered suitable validation of certification status.
 During the BRC Global Standards audit the site may be asked to demonstrate its validation process
 - confirmation that the certification remains up to date (e.g. by receiving confirmation of successful completion of the recertification processes or by recording certificate expiry dates and completing checks for ongoing certification)
 - ensuring that the activities are within the scope of the certification.

A successful site audit covers at a minimum product safety, traceability, HACCP and good manufacturing processes. This audit must be completed by an appropriately experienced and competent auditor (i.e. someone who has completed training in auditing techniques, has experience of auditing, and has knowledge of the product, ingredient or processes being audited). Non-conformities should be addressed (e.g. in an agreed action plan with timescales) unless they are critical to product safety or legality, in which case supply should not be permitted until the non-conformities have been satisfactorily addressed. If the outside processor is independently audited to another standard that is not GFSI-benchmarked, this may be acceptable as an alternative to the site completing its own audit of the processor providing that:

- the scope of the audit meets the requirements of the Standard (i.e. at a minimum product safety, traceability, HACCP review and good manufacturing practices)
- the site has a copy of the full audit report (not just a certificate)
- the processor can demonstrate the competence of the auditor.

CLAUSE	REQUIREMENTS
	Where risk assessment (completed as part of this clause) indicates that a processor is low risk (e.g. due to history of outsourcing to the processor or the nature of the activities) the completion of a questionnaire with a focus on food safety and quality may be sufficient. If a questionnaire is the only mechanism used to assess an outside processor (i.e. there are no additional activities such as audits), then it is important that the questionnaire (and replies from the processor) contains all the relevant information to allow the site to confidently make a decision on approval.
	The auditor will expect to see, and will challenge, risk assessments. The site must be able to demonstrate to the auditor that the monitoring and ongoing review it uses is appropriate, justified and risk-based.
3.5.4.3	Any outsourced processing operations shall:
	 be undertaken in accordance with established contracts which clearly define any processing and/or packing requirements and product specification maintain product traceability.
Interpretation	Contracts and traceability Contracts must be in place for the approved processors detailed in clause 3.5.4.2 to ensure:
	 the correct level of service is provided the processing or packing requirements are clearly defined in terms of the work to be undertaken, the product, ingredient specification, and any relevant safety, quality, legality or authenticity requirements.
	There must be documented mechanisms to ensure traceability is maintained throughout the process.
	Records relating to the traceability of individual batches of processed ingredient or product must be available.
3.5.4.4	The company shall establish inspection and test procedures for products where part of the processing has been outsourced, including visual, chemical and/or microbiological testing.
	The frequency and methods of inspection or testing shall depend on risk assessment.
Interpretation	Acceptance and test procedures A documented acceptance procedure must identify the checks to be made when outsourced processing is complete. When products that have been processed are returned to the site, this procedure could form part of the goods receipt system.
	Acceptance procedures may, for example, include:
	 visual inspection chemical, microbiological or allergen testing hold/release requirements for the specific material (e.g. to allow additional testing or quality assurance checks).
	The requirements (both acceptance methods and the frequency of any checks or tests) must be based on risk assessment of the nature of the ingredient or product, the process and the outside processor undertaking the processing; for example, the processor may handle allergens that could potentially contaminate the processed product.
	The acceptance procedure must document any non-conformities, the person(s) authorised to accept conforming materials and reject non-conforming batches, and the action to be taken in the event of a non-conformity.

3.6 SPECIFICATIONS

Specifications shall exist for raw materials (including primary packaging), finished products and any product or service which could affect the integrity of the finished product.

Interpretation

The company must be assured of the quality of the products purchased. This includes any raw material or service that can affect food safety – for example, water and cleaning chemicals used, as well as services such as pest control, cleaning services or distribution.

Specifications for in-house intermediate products (work in progress) must be developed where they need to be checked and where they have an impact on product safety, legality and quality.

A finished product specification must exist for all products covered under the certification scope, which ensures that required legislation and customer expectations are achieved.

Specifications must also be available for any product or service that can affect the integrity of the finished product. These should be sufficiently detailed to allow the company to understand and agree the product or service parameters; for example, specifications for cleaning chemicals should contain details on the components, usage instructions and material safety data.

Current specifications must be available for relevant personnel in order to ensure the specifications are being appropriately fulfilled. This may be the complete specification or parts thereof, or relevant details may be developed as production reference sheets, such as simple photographic specifications.

CLAUSE	REQUIREMENTS
3.6.1	Specifications for raw materials and primary packaging shall be adequate and accurate and ensure compliance with relevant safety and legislative requirements. The specifications shall include defined limits for relevant attributes of the material which may affect the quality or safety of the final products (e.g. chemical, microbiological or physical standards).
Interpretation	Raw material and packaging specifications Specifications for all raw materials, including primary packaging materials, must be provided and adequate detailed. They must include the defined limits for all parameters critical to the safety, legality and quality of the product. They must also include details of packaging.
	The specifications may be in the format provided by the supplier or in the company's own format, as long as the information controlling the product's quality and safety are clearly defined.
3.6.2	Accurate, up-to-date specifications shall be available for all finished products. These may be in the form of printed or electronic document, or part of an online specification system.
	They shall include key data to meet customer and legal requirements and assist the user in the safe usage of the product.
Interpretation	Finished product specifications Specifications must be in place detailing all finished products. These specifications must be up to date (i.e. they must accurately represent the current version of the product) and should be reviewed whenever changes occur to the product, process or formulation.
	The format of the specifications should be agreed with the customer to ensure that all relevant customer requirements are incorporated. This may, for example, be printed documents, electronic files or an online database. In the case of the company's branded products, it is acceptable to have an internal specification setting parameters for the manufacture of a product and a technical data sheet for customer use containing the key information for the safe use of the product, including but not limited to:
	 ingredients, including the presence of allergens nutritional information preparation or cooking instructions storage instructions shelf-life/code information quantity.
	Specifications must be accurate and the control of amendments and approval of specifications should therefore be laid down in a documented procedure. This procedure should also detail who can approve the amendments.
3.6.3	Where the company is manufacturing customer-branded products, it shall seek formal agreement of the finished product specifications. Where specifications are not formally agreed then the company shall be able to demonstrate that it has taken steps to ensure formal agreement is in place.
Interpretation	Formal agreement of specifications Customer-branded, finished product specifications must be formally agreed with the relevant customer an must, wherever possible, be signed by both parties. However, where the customer's signature or approval

not formally available, proof that specifications have been issued (such as an email request for formal acknowledgement or specifications on customer IT specification systems) is required. In this situation the

site must be able to demonstrate it is following a formal process agreed with the customer.

CLAUSE	REQUIREMENTS
3.6.4	Specification review shall be sufficiently frequent to ensure that data is current or at a minimum every 3 years, taking into account product changes, suppliers, regulations and other risks.
	Reviews and changes shall be documented.
Interpretation	Review of specifications Specifications must be reviewed whenever changes occur to the product, process or formulation. Where no known changes have occurred, the specifications must be reviewed at least every 3 years, or more frequently if required by a specific customer, to ensure they remain completely up to date and accurate. Evidence that a review has been completed needs to be available and this should be achieved through the addition of a signature and date to the specification or through the use of a matrix showing specifications and the latest review date and reviewer.
	The control of the amendment and approval of specifications should be laid down in a documented procedure. The procedure should also detail who can approve the amendments.
	Some sites, companies or customers use cloud-based services which are able to notify the user when there has been a change to the data. In these cases, the site should have a mechanism to review the specification or change to understand whether there is any impact to product safety, the HACCP or food safety plan, or the production processes. This requirement is also reflected in clause 2.14.1, which explains how the HACCP or food safety plan needs to be reviewed whenever raw materials change.

3.7 CORRECTIVE AND PREVENTIVE ACTIONS

FUNDAMENTAL

The site shall be able to demonstrate that it uses the information from identified failures in the food safety and quality management system to make necessary corrections and prevent recurrence.

Interpretation

The objective is to ensure there are clear procedures to deal with problems that have the potential to affect safety, legality or quality, ensuring that the finished product and consumer safety are not compromised. This must include immediate actions and an analysis of the overall issues so that long-term preventive actions may be put in place.

CLAUSE	REQUIREMENTS
3.7.1	The site shall have a procedure for handling and correcting failures identified in the food safety and quality management system.
Interpretation	Management of corrective actions There must be a documented procedure for handling failures in the food safety and quality system. All failures or non-conformities generated by the site (e.g. non-conforming product, internal audits, third-party audits or customer complaints) must be subject to corrective action.
	Good practice is for corrective action to be completed as soon after detecting the non-conformity as possible (this is particularly important where the non-conformity could affect product safety, legality or quality – see clause 3.7.2).
Further guidance	Do all non-conformities need correction? All non-conformities generated by or occurring at a site need to be subjected to corrective action. This may include, for example, non-conformities or problems identified by:
	 staff, particularly those in production areas who are in a prime location to raise the alarm if any product, ingredient or process is outside predefined limits internal audits third-party audits (including the site's BRC Global Standard audit) management review activities product testing (including product inspection, quality assurance checks or laboratory testing)

- monitoring of production processes (e.g. CCP monitoring)
- customer complaints
- information from regulatory authorities (e.g. product testing or site visits).

Documentation and records

Two types of documentation are required:

- a corrective action procedure that details the process for handling non-conformities. This should include:
 - assessment of the consequences of the non-conformity
 - identification of the competent and authorised individual(s) responsible for investigating the non-conformity and deciding the appropriate response
 - activities that must be completed as part of the process, including deciding actions, setting
 timescales for the completion of actions, assigning responsibility for actions to specific individuals,
 verifying the completion of actions, completion of root cause analysis and preventive action.
- records of each non-conformity and subsequent action taken, including:
 - details of the non-conformity, when it occurred and how it was identified
 - details of the actions taken
 - dates when the actions were completed
 - verification that the actions were completed and effective
 - root cause analysis and preventive action.

3.7.2

Where a non-conformity places the safety, legality or quality of products at risk, this shall be investigated and recorded including:

- clear documentation of the non-conformity
- assessment of consequences by a suitably competent and authorised person
- the action to address the immediate issue
- an appropriate timescale for correction
- the person responsible for correction
- verification that the correction has been implemented and is effective.

Interpretation

Non-conformities with associated safety, legality or quality risks

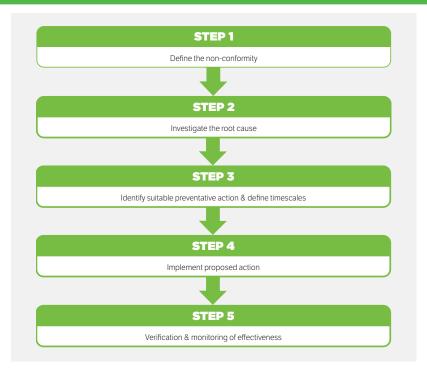

Non-conformities with the potential to affect product safety, legality or quality must be recorded, and the responsibility for investigating the cause of problems and ensuring that an adequate response is taken must be assigned to specified personnel.

Action needs to be undertaken as soon as possible after the detection of the non-conformity, but there may also be a need for long-term action to prevent further occurrence of the non-conformity. All actions undertaken must be documented.

The records will include:

- details of the non-conformity and when it occurred or was identified
- assessment of the potential consequences of the non-conformity by a suitably competent and authorised person
- details of the action taken to address the immediate issue and dates or timescales for completion of the actions
- identification of who is authorised and responsible for the actions
- details of the verification checks to ensure the action has been implemented and is effective.

The actions should be included in a regular review of activities and systems. If timescales for actions are not met, the reasons should be recorded. Where an identified non-conformity may affect other products, then any possible consequences need to be identified and appropriate action taken.

Procedure for dealing with non-conformities

Further guidance

Timeliness of actions

All corrective actions should be completed in a timely fashion. In practice this will depend on the nature of the activity and the potential consequences of a delay. For example, stopping the production line would happen immediately but receiving and fitting a new or replacement part may be a prolonged process.

The site must assess the consequences of any delay in action and ensure that product integrity and safety are not jeopardised. Where set timescales are not met, the reason for the delay should be recorded and reviewed by the appropriate site management to ensure ongoing product safety and, where necessary, provide appropriate resources.

3.7.3

The site shall have a procedure for the completion of root cause analysis. At a minimum root cause analysis shall be used to implement ongoing improvements and to prevent recurrence of non-conformities when:

- analysis of non-conformities for trends shows there has been a significant increase in a type of non-conformity
- a non-conformity places the safety, legality or quality of a product at risk.

Interpretation

Root cause analysis

When errors occur, such as non-conforming product, product recalls or non-conformities raised at audits, the site should prevent recurrence of these errors using root cause analysis. This is not a generally prescribed set of actions or activities, but comprises a set of tools that can be deployed where required to determine the true cause of an error.

Some clauses in the Standard specifically require root cause analysis but it is up to the site to establish a procedure for its completion. Root cause analysis should include:

- a set of parameters that will initiate the use of an appropriate tool (i.e. the site must define when the analysis will be completed if it is not already prescribed by the Standard)
- who is trained and/or authorised to complete the analysis
- the methods that the site will use to conduct the analysis
- the records which detail the analysis and any subsequent preventive actions
- the methods for the verification of the completed actions.

The auditor will expect to see a documented procedure that includes this information, as well as evidence of any root cause analysis and preventive action that the site has carried out.

Further guidance

Root cause analysis

An important part of an effective corrective action process is the identification of the root or underlying cause of the non-conformity and the implementation of suitable action to prevent recurrence. Root cause analysis is a process of conducting an investigation into an identified problem to allow the investigator(s) to understand the fundamental cause and put it right. While there are a number of techniques for undertaking root cause analysis, one of the most common and simplest to use is the 'five whys' technique. The technique is based on repeatedly digging deeper into the cause of a problem by asking 'Why ...?' to get to the root of the issue. Usually, the root cause becomes evident after five steps, but this is not fixed and further investigation should be completed where required.

Example

The five whys technique

An operator is instructed to perform a simple action, 'Weigh out ingredient A'. However, the operator inadvertently uses ingredient B instead. The immediate reaction would probably be that this was operator error. Although this may be accurate, it does not establish the reason why the error occurred or prevent it from happening in the future. Using the five whys technique, the root cause analysis should ask and answer a series of questions:

- Why did the operator make the error? The operator was unfamiliar with the procedure.
- Why was an operator who was unfamiliar with the procedure asked to complete it? He had been trained but there was no supervision or sign-off of the training to confirm it was satisfactory.
- Why was the training not satisfactory? The two ingredients looked identical.
- Why weren't the ingredients clearly labelled? The labels had been removed during cleaning and not replaced.
- Why weren't the labels replaced? The cleaning staff did not consider the significance of the delay or the potential for an error.
- Why were the ingredient containers being used if they had not been set up correctly for manufacture? Checking the labels did not form part of anyone's duties.

The conclusion of a root cause analysis should be to identify what should be changed to prevent recurrence of the error. In this example, the conclusion might be to:

- update the training procedure
- introduce a training sign-off procedure to ensure training is understood
- replace labels if practical, with ones that cannot be removed. Where labels must be removed occasionally, ensure that post-maintenance line checks include a check of signage
- ensure that an individual (e.g. the production manager) is authorised and responsible for post-cleaning line sign-off
- ensure that cleaning staff fully understand and are trained in the need to return labelling (and all equipment) to a fully operational state.

Now that the root cause analysis has been completed, it is easy to see how this incident occurred. The causes were:

- an incomplete training procedure
- a faulty cleaning process
- lack of post-cleaning check procedures.

The next step of the process is for the site to identify and implement suitable preventive action to ensure the problem does not occur again (where a non-conformity has multiple causes it is important that the preventive action addresses all of these). For example:

- update the training procedure to ensure sign-off (and possibly a supervision step)
- replace ingredient labels ideally with ones that cannot be removed
- if labels must occasionally be removed, ensure that post-cleaning line checks include a signage check
- ensure an individual is authorised and responsible for post-cleaning line sign-off
- ensure cleaners fully understand and are trained in the need to return labelling (and all equipment) in a fully operational state.

BRC Global Standards has produced a guideline on root cause analysis which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

CLAUSE	REQUIREMENTS
Quick tips	 Train staff in any new requirements resulting from corrective and preventive action. Ensure root cause analysis is completed so that effective preventive controls can be established.

3.8 CONTROL OF NON-CONFORMING PRODUCT

The site shall ensure that any out-of-specification product is effectively managed to prevent unauthorised release.

Interpretation

The objective is to ensure there are clear documented procedures to deal efficiently with any non-conformity that has the potential to affect product safety or quality. There is also a need to ensure that any non-conforming product or raw material is physically removed from the production process.

CLAUSE	REQUIREMENTS
3.8.1	 There shall be procedures for managing non-conforming products. These procedures shall include: the requirement for staff to identify and report a potentially non-conforming product clear identification of a non-conforming product (e.g. direct labelling or the use of IT systems) secure storage to prevent accidental release (e.g. physical or computer-based isolation) referral to the brand owner where required defined responsibilities for decision-making on the use or disposal of products appropriate to the issue (e.g. destruction, reworking, downgrading to an alternative label or acceptance by concession) records of the decision on the use or disposal of the product records of destruction where a product is destroyed for food safety reasons.
Interpretation	Management of non-conforming product The control of non-conforming product must be described in a documented procedure (in this context the implicated product could be any material, such as an ingredient, final product, packaging, or a combination of these). Procedures must include:

- · ensuring that all staff are aware of the need to report issues that may affect product safety, quality or legality, and to whom. This may be covered as part of the induction process for production staff
- the system for labelling and identification of non-conforming product. This may include both direct labelling and computer-based records
- segregation or isolation of non-conforming product. Ideally, the product must be physically segregated by moving it to an identified area within the production site, or clearly marked so that it cannot be confused with in-process material or finished product. The use of electronic inventory systems to 'electronically isolate' the material is also acceptable
- referral to the brand owner where required. The brand owner may need to be notified of quality issues and would expect to be contacted where issues affect product safety. Agreement may need to be reached before the held products are released for sale. Contacting brand owners is not usually necessary where the decision is to destroy, downgrade or rework product, unless this notification is a contractual requirement of the brand owner
- details of staff responsibilities, including which staff are authorised and responsible for decisions relating to non-conforming products. The final decision on what to do with held product should be taken by an experienced, technically competent manager. Only a limited number of personnel must have the authority to lift the hold notice or remove product from the isolation area
- records of all products placed on hold. These must include:
 - details of the product quantity and code
 - the reason for isolation
 - action taken or required to assess the suitability of the product
 - the final decision on what to do with the product
 - the name of the person authorising the decision and date
 - confirmation of the action taken
 - any further actions required to prevent recurrence (this may link to an investigation of corrective actions; see section 3.7)

cLAUSE REQUIREMENTS the 'on hold' procedure employed while an investigation is completed procedures for the effective safe disposal of product. It is usual to maintain a log of products which are on hold and to undertake periodic physical checks of held stock to ensure that accidental release has not occurred. The summary of products held and actions taken must be reviewed as part of the management review process. Non-conforming product is a key prompt to initiate root cause analysis, particularly when there has been an

increase in incidents of the same type (e.g. mis-packing).

3.9 TRACEABILITY

FUNDAMENTAL

The site shall be able to trace all raw material product lots (including primary packaging) from its suppliers through all stages of processing and dispatch to its customers and vice versa.

Interpretation

As well as being a legislative requirement, traceability is a risk management tool, allowing food businesses and authorities to withdraw or recall products that have been identified as unsafe. It is therefore a fundamental requirement. A traceability system needs to be established at all stages of production, processing and distribution, identifying from whom raw materials have been obtained and to which customers finished product has been supplied. Note that the Standard requires forward and backward traceability throughout the production process. This means that the site should know where the material has come from (i.e. the direct supplier) and to whom finished product is dispatched. There is no requirement for the site to trace raw materials all the way back to the source (e.g. farm) unless the source is the direct supplier to the site.

The system must ensure that products supplied to customers are adequately labelled or identified to facilitate traceability. Traceability details need to be retained in a format that allows access in a timely manner.

BRC Global Standards has published a traceability guideline which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

CLAUSE	REQUIREMENTS
3.9.1	The site shall have a documented traceability procedure designed to maintain traceability throughout the site's processes. At a minimum this shall include:
	how the traceability system worksthe labelling and records required.
Interpretation	Traceability procedure Sites are free to utilise their own traceability systems; no specific tool or technique is required by the Standard. Nevertheless, it is imperative that the site documents its traceability procedure so that it can be used and understood by the relevant personnel. This is particularly important at times of stress, when it is likely that the procedure will be relied upon to ensure at-risk product is identified and recalled or withdrawn in a timely manner.
3.9.2	Identification of raw materials (including primary packaging), intermediate/semi-processed products, part-used materials, finished products and materials pending investigation shall be adequate to ensure traceability.
Interpretation	Identification of raw materials and finished product Products and materials may be identified by physical labelling, by recording systems identifying the allocation of materials to production or mixing areas, or through the use of computerised bar-coding systems. The level of traceability may need to be agreed between the company and its customers, but the

finished product to be identified if a particular batch of raw material needs to be recalled.

system used must be capable of linking all raw material lot codes to finished product codes. This will enable

CLAUSE

REQUIREMENTS

The limitations of any system must be recognised, as can be demonstrated by the problems associated with bulk storage. Products such as sugar may be delivered with clear batch identification; however, if they are emptied into a single storage tank that is mixed with earlier deliveries, the reduction in accurate traceability is compounded by the potential for product to be trapped in dead zones during filling and emptying. If a particular delivery is identified as being contaminated, the entire product in the storage tank would need to be disposed of, as well as several lot codes of finished product, as the company would not be able to identify the specific batch of finished product that contained the contaminated material.

The traceability system needs to include primary packaging (i.e. packaging in direct contact with food). Note that processing aids (i.e. substances that are used within the process but are not required to be declared as an ingredient, such as sodium alginate for the clarification of beer) are included in the definition of raw materials (see glossary, Appendix 2) and therefore need to be included in the traceability system.

All test results (clause 3.9.3) must be traceable to specific batches of product or ingredient.

Consider how the traceability system operates in practice (with the effective physical identification of ingredients and products). For example, if bulk containers are labelled, consider how the information is presented to ensure it is legible and accurate. Common non-conformities include the ineffective labelling of part-used packs in production and storage areas leading to potential errors.

Strict controls on material identification, traceability and segregation are also required to preserve the integrity of any claims made, such as organic status. Where logos are used that make specific claims about production systems (e.g. farm assurance), full traceability must be demonstrated (see also section 5.4).

Apart from batch or lot codes, traceability information will usually include date codes to ensure that only ingredients, intermediates and products within the appropriate shelf-life period are used. Particular care is needed for decanted ingredients, work in progress and products stored in bulk where the packaging has been removed.

3.9.3

The site shall test the traceability system across the range of product groups to ensure traceability can be determined from the supplier of raw material (including primary packaging) to the finished product and vice versa, including quantity check/mass balance.

The traceability test shall include a summary of the documents that should be referenced during the test, and clearly show the links between them. The test shall occur at a predetermined frequency, at a minimum annually, and results shall be retained for inspection. Traceability should be achievable within 4 hours.

Interpretation

Tests of the traceability system

The site's traceability system must be tested at least annually, or more frequently if required by a customer. (Note that the frequency of traceability tests relating to provenance and origin claims is covered separately in clause 5.4.4.)

Where traceability for all products manufactured by the site is the same or similar, then a minimum of one traceability test a year must be completed. However, if there are significant differences or specific traceability challenges relating to one product or group of products, additional tests specifically related to that product or group of products may be needed.

Traceability testing may be completed as part of a real product recall or withdrawal scenario if one has occurred, since the objective is to test the system and identify areas for improvement, rather than supply records of a 'test' for its own sake.

The system must provide traceability forwards and backwards; therefore the system should be tested in both directions. For example, a raw material could be selected and traced forwards to show in which finished products it was used. A finished product should also be selected and traced backwards to show all the raw material batch codes (including primary packaging) that were used to produce it. The tests should include identifying which customers received the finished products and which suppliers provided the raw materials. The traceability test must also include the traceability of the primary packaging materials.

The test of traceability should be timed and full traceability would be expected to be achieved within 4 hours. This is to reflect the need for rapid traceability in the event of a recall. Where traceability takes longer than 4 hours, review the areas where the retrieval of information is slow in order to identify improvements.

CLAUSE

REQUIREMENTS

The tests must also include a quantity check or mass balance exercise. It is not expected that the full mass balance exercise would always be achievable within 4 hours. The objective is to be able to account for the usage of a full batch of a raw material. This helps to ensure that the traceability systems are capable of operating effectively should a product recall be required based on the recall of an ingredient.

The mass balance exercise is usually undertaken as follows:

- Select a batch code of a particular specific raw material.
- Identify the quantity of the raw material supplied under that batch code.
- Identify the recipes in which the ingredient is used.
- Use production schedules and batch make-up sheets to calculate the quantities of the selected batch of ingredient used in each product.
- Calculate the quantity of any unused part of the batch in the warehouse.
- Reconcile the quantity delivered against the amounts used plus any residual unused stock.

In some instances quantity checks may take a great deal of time and resource to complete successfully.

It is unlikely that the mass balance exercise will be able to account for all materials to 100% accuracy. However, the company needs to justify any discrepancies and demonstrate understanding of the nature of the variance. This may be inherent in the product characteristics (e.g. dehydration of fresh ingredients), or be ascribed to typical wastage on equipment or portion variances. Where the site adds subsequent deliveries to a bulk silo, the test should clearly show how this has been managed. The principle is to ensure that the traceability system is effective. Mass balance is a key measure of its workability and highlights areas for improvement.

During the BRC Global Standard audit, the auditor will ask the site to complete a full 'vertical' audit. At a minimum this will include the traceability of a specific batch of product or ingredient through the site's production, processing and distribution processes, and a review of the site records related to the product or ingredient. Records will include, for example, supplier approval, goods receipt, process records (such as temperature monitoring), metal detector checks and dispatch records. However, the vertical audit is not expected to include records that would only be held at other points in the supply chain (e.g. the raw material supplier's processing records).

The vertical audit will also include a mass balance exercise and a review of the systems relating to the accuracy of labelling (clause 5.2.1). Further information on the content of the audit, including the vertical audit, can be obtained from BRC Global Standards' guide to auditing techniques. This may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

3.9.4

Where rework or any reworking operation is performed, traceability shall be maintained.

Interpretation

Rework

Where rework of products or processes is undertaken, consider whether this will affect the product (e.g. whether the ingredient declaration on the product will need to be changed). Procedures must be in place to ensure that traceability is maintained, and in addition that the safety or legality of products is not affected.

Further quidance

What to expect at the certification audit

During all BRC Global Standard certification audits, a traceability test and vertical audit will be carried out on a product selected by the auditor, which must have typically been produced in the 2–5 months prior to the audit date. Where a claim is made about a component of the product (section 5.2), the test must include the mass balance of the material subject to the claim. The mass balance exercise should be in both directions (i.e. finished product to raw material and vice versa). It is recommended that the vertical audit (i.e. traceability documentation plus all associated production and raw material documentation) is carried out only as part of the trace backwards from finished product to raw materials. To undertake such an exercise in both directions would be too time-consuming unless issues are expected. Where any of the site's products make a claim of provenance (clause 5.4.4), the product selected for the traceability study should be one for which such a claim is made.

Details will be recorded by the auditor and summarised in the final audit report.

This vertical audit is in addition to the review of the company's own traceability checks. The method of achieving traceability will also be reviewed as part of the audit of production areas.

BRC Global Standards publishes a separate best-practice guideline on traceability, which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

3.10 COMPLAINT-HANDLING

Customer complaints shall be handled effectively and information used to reduce recurring complaint levels.

Interpretation

Complaints are key sources of information that may require escalation into emergency plans such as a product withdrawal or recall. Therefore, an effective complaint-handling system needs to be operated by the company. Complaints are also a key measure of product quality and identify opportunities for continual improvement. The objective of the complaint investigation process should be to identify and correct causes of complaints, and one measure of an effective system should be a reduction in the number of complaints as a proportion of production volume.

CLAUSE	REQUIREMENTS
3.10.1	All complaints shall be recorded, investigated and the results of the investigation of the issue recorded where sufficient information is provided. Actions appropriate to the seriousness and frequency of the problems identified shall be carried out promptly and effectively by appropriately trained staff.
Interpretation	Documentation and action The company should ensure there is a clear process for customers (and potentially consumers too) to raise legitimate complaints about the products. This is usually via the contact information on product labels. Where products are supplied into food service or through intermediaries, every effort should be made to ensure that complaints raised are relayed to the complaints department of the site.
	All complaints need to be captured to a specified location to ensure they are adequately assessed and investigated, and the results of this investigation recorded. A documented complaints procedure is therefore required and the inclusion of a standardised complaint form may be useful.
	Complaints must be handled by appropriately trained staff to ensure that a proactive system identifies the severity, and therefore the significance, of any complaints received. Actions must be appropriate to the seriousness of the complaint. A rapid response would be required for serious issues (such as a glass complaint) or where a number of complaints are received, suggesting a widespread problem.
	Investigation must be completed within a defined timeframe and feedback provided to the complainant wherever contact details are provided.
3.10.2	Complaint data shall be analysed for significant trends. Where there has been a significant increase in a complaint or a serious complaint, root cause analysis shall be used to implement ongoing improvements to product safety, legality and quality, and to avoid recurrence. This analysis shall be made available to relevant staff.
Interpretation	Trend analysis Data on customer complaints must be analysed to identify trends. A root cause analysis should be carried out where there is evidence of an emerging trend or a serious complaint. This is to help ensure problems are identified and improvements made to prevent recurrence as far as practicable.
	This may include, for example, an analysis of foreign-body complaint types as complaint numbers per number of units produced, with data by shift or by production line. This data must be communicated to relevant staff and may include graphical displays on staff noticeboards or discussion at routine operations meetings.
	Trend analysis may demonstrate that certain complaints are associated with customer abuse of the product (e.g. not following cooking instructions). A root cause analysis of these complaints should be undertaken to establish whether the underlying cause can be managed by the company. For example, could on-pack instructions be made clearer to reduce customer abuse and therefore the number of complaints?
	BRC Global Standards publishes a separate best-practice guide to complaint-handling, which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

3.11 MANAGEMENT OF INCIDENTS, PRODUCT WITHDRAWAL AND PRODUCT **RECALL**

The company shall have a plan and system in place to manage incidents effectively and enable the withdrawal and recall of products should this be required.

Interpretation

Incidents are events that may result in the production of unsafe, illegal or non-conforming product and risks to consumer safety. An emergency situation may also occur as a result of a sudden, unforeseen crisis that requires immediate action. An effective emergency plan must be in place so that if, at any stage, an incident occurs that impacts food safety, legality or quality, it will be managed effectively. The incident may be directly related to the product, the disruption of key services such as power and water, or environmental influences such as fire or flood.

The plan must be understood by relevant staff and must be routinely tested so that it can readily be put into practice, as incidents occur when least expected. The importance of a tried and tested procedure, ensuring that personnel know who does what and when, cannot be underestimated.

CLAUSE	REQUIREMENTS
3.11.1	The company shall have procedures designed to report and effectively manage incidents and potential emergency situations that impact food safety, legality or quality. This shall include consideration of contingency plans to maintain product safety, quality and legality. Incidents may include:
	 disruption to key services such as water, energy, transport, refrigeration processes, staff availability and communications events such as fire, flood or natural disaster malicious contamination or sabotage failure of, or attacks against, digital cyber-security.
	Where products which have been released from the site may be affected by an incident, consideration shall be given to the need to withdraw or recall products.
Interpretation	Documented incident and emergency procedures In the event of an incident or emergency situation, the company must be ready to instigate actions as promptly and efficiently as possible. The objective of the plan must be to minimise risk to consumers and potential disruption to business. Systems must be in place and used to ensure that information is collated and quickly assessed by staff who understand its significance and who can develop an appropriate action

and quickly assessed by staff who understand its significance and who can develop an appropriate action plan. The site might establish a crisis management plan that could address the points listed here, and any additional risks which are outside the scope of the Standard.

A documented incident management procedure is required. Although it may not be possible to detail exactly what action will be taken, as this will depend on individual circumstances, the company should consider:

- standard responses to a range of potential disasters, such as fire, flood or the loss of essential services
- the provision of alternative resources for energy, water, transport and any potential options for subcontracting production
- how to handle acts of potential malicious contamination or extortion
- details of staff responsibilities, including which staff are authorised and responsible for making decisions relating to non-conforming products
- methods to communicate with key contacts, both internal and external, such as telephone and email contact details (including office hours and out-of-hours details)
- corrective action that needs to be taken before production can recommence.

These details must be kept up to date by periodic verification. Customers and suppliers may need to be involved in the development of documented procedures as they may have their own requirements for crisis planning.

CLAUSE

REQUIREMENTS

With more data being stored digitally and in cloud services, the site needs to be aware that such data is valuable to those who might extort or blackmail companies. Even though cloud services can be relatively secure, digital attacks and failures of systems pose a significant risk and the site needs to ensure that digital data is secure by using, for example, password protection, anti-virus software, firewalls and/or data back-up systems.

Some organisations have published advice on cyber security; for example, the National Cyber Security Council's *10 Steps to Cyber Security* (www.ncsc.gov.uk/guidance/10-steps-cyber-security).

3.11.2

The company shall have a documented product withdrawal and recall procedure. This shall include, at a minimum:

- identification of key personnel constituting the recall management team, with clearly identified responsibilities
- guidelines for deciding whether a product needs to be recalled or withdrawn and the records to be maintained
- an up-to-date list of key contacts (including out-of-hours contact details) or reference to the location of such a list (e.g. recall management team, emergency services, suppliers, customers, certification body, regulatory authority)
- a communication plan including the provision of information to customers, consumers and regulatory authorities in a timely manner
- details of external agencies providing advice and support as necessary (e.g. specialist laboratories, regulatory authority and legal expertise)
- a plan to handle the logistics of product traceability, recovery or disposal of affected product, and stock reconciliation
- a plan to record timings of key activities
- a plan to conduct root cause analysis and to implement ongoing improvements, to avoid recurrence.

The procedure shall be capable of being operated at any time.

Interpretation

Documented withdrawal and recall procedure

A product recall is defined as any activity that involves the return of an unfit product from customers and final consumers, whereas a withdrawal is the return of out-of-specification or unfit products from customers, but not from final consumers.

The site must have a documented recall and withdrawal procedure. At a minimum, it must include:

- details of the recall management team members, including their roles, responsibilities and contact
 details. In larger businesses the recall team will involve head office personnel and it may be run from the
 head office. In this case the links between the production-site management and the recall team need to
 be clear
- guidelines for deciding whether a product needs to be recalled or withdrawn and the records to be maintained. Although causes for recall are often unpredictable, defined responses to known risks (e.g. identification of pathogens in routine product sampling) could be documented
- an up-to-date list of key contacts (e.g. recall management team, suppliers, customers, the certification body and regulatory authorities). A recall may occur at any time, therefore office-hours and out-of-hours contact details must be provided
- a communication plan including the provision of information to customers, consumers and regulatory
 authorities in a timely manner. The communication process and the way in which enquiries from
 customers and the media are handled can be critical to the effective management of the situation and
 ultimate business recovery. The use of professional resources to assist in communication management
 may sometimes be advisable
- details of external agencies providing advice and support as necessary (e.g. specialist laboratories, regulatory authorities and legal expertise)
- a plan to handle the logistics of product traceability, recovery or disposal of affected product and stock reconciliation
- a log of activities created as the event unfolds and real-time observations, which could, for example, be used in discussions with customers or regulatory authorities. This may be valuable during a post-incident review to consider improvements to incident management processes
- reference to the root cause analysis procedure, so that relevant preventive actions can be introduced.

CLAUSE	REQUIREMENTS
3.11.3	The product recall and withdrawal procedures shall be tested, at least annually, in a way that ensures their effective operation. Results of the test shall be retained and shall include timings of key activities. The results of the test and of any actual recall shall be used to review the procedure and implement improvements as necessary.
Interpretation	Tests of the withdrawal and recall procedures The withdrawal and recall procedure must be tested at least annually. It should be emphasised that traceability is only part of this procedure. The aims of testing the full procedure are to:
	 demonstrate that the system works highlight any gaps and where the system requires improvement demonstrate how quickly the required information can be collated, and thereby corrective action taken, such as materials being isolated and quarantined act as a training exercise for personnel to ensure that clear roles and responsibilities are undertaken in the event of a real withdrawal situation.
	The test of the recall and withdrawal procedure must include verification of the decision-making process, traceability of raw materials through to finished product, verification of contacts, and timings of key activities.
	Records must be kept of tests of the recall and withdrawal procedure and must include a review of the result of the test and any action taken for improvement.
	If the site has had an actual withdrawal or recall which fully tested its recall procedures, then this would be a substitute for a recall test as long as records are maintained, an analysis of the effectiveness of the recall procedure is carried out, and any areas for improvement are identified and acted upon.
3.11.4	In the event of a significant food safety incident, including a product recall or regulatory food safety non-conformity (e.g. a regulatory enforcement notice), the certification body issuing the current certificate for the site against this Standard shall be informed within 3 working days.
Interpretation	Notification of recalls to the certification body The aim of this notification is to ensure that the integrity of the certificate is maintained by allowing the certification body to assess whether the incident affects the certification status of the site. Therefore the certification body needs to be notified of all significant food safety incidents (including all product recalls and regulatory food safety enforcement actions) relating to product that is manufactured or processed on site. Where appropriate, the certification body can request further information or conduct a full or partial re-audit of the site to confirm certification.
	It is important that action is taken in a timely manner (i.e. within 3 working days). There is no requirement to notify the certification body of a product withdrawal.

4 SITE STANDARDS

4.1 EXTERNAL STANDARDS

The production site shall be of suitable size, location and construction, and be maintained to reduce the risk of contamination and facilitate the production of safe and legal finished products.

Interpretation

This part of the Standard is one of the most straightforward. It requires that the manufacturing facility is fit for purpose, both externally and internally, and that operations are conducted in an orderly fashion so as not to jeopardise the safety or quality of the product.

CLAUSE	REQUIREMENTS
4.1.1	Consideration shall be given to local activities and the site environment, which may have an adverse impact on finished product integrity, and measures shall be taken to prevent contamination. Where measures have been put into place to protect the site (from potential contaminants, flooding etc.), they shall be reviewed in response to any changes.
Interpretation	Local activities and site environment Local activities and the site environment must not have an adverse impact on finished product integrity. (A site plan or map that indicates neighbouring activities may be useful.) Points to consider may include:
	 derelict buildings, rubbish dumps, wasteland etc. which could harbour pests adjacent watercourses at risk of flooding neighbouring companies and the nature of their business (e.g. presenting air or odour taint potential).
	Appropriate measures, such as additional pest or flood control, must be put in place and reviewed to ensure they are continually effective (e.g. by inclusion on internal audit schedules).
4.1.2	The external areas shall be maintained in good order. Where grassed or planted areas are located near buildings, they shall be regularly tended and well maintained. External traffic routes under site control shall be suitably surfaced and maintained in good repair to mitigate the risk of contamination of the product.
Interpretation	Maintenance of external areas External areas must be maintained in good order and the condition of the site included in audit procedures. Overgrown areas can harbour pests; therefore, where areas are planted, they must be tended regularly. For example, good practice is to have a 0.5 m clear zone between the bottom of vegetation and external walls.
	Drainage in external areas is expected to deal with normal quantities of rainfall without long-term pooling of water. If natural drainage is inadequate, external drainage must be installed.
	To prevent potential contamination by dust, mud etc., all traffic routes under the control of the company must be suitably surfaced and maintained in good order. It is recognised that traffic routes may have a variety of surfaces, and contamination risk to products will be influenced by other factors, such as weather conditions. The principle is to ensure that products are not placed at additional risk of contamination through the inappropriate surfacing of routes where products are transferred. Risk may also be reduced by a combination of procedures, such as the suitable protection of products while in transit, or wash-down of transit vessels prior to entering production areas.
4.1.3	The building fabric shall be maintained to minimise potential for product contamination (e.g. elimination of bird-roosting sites, sealing gaps around pipes to prevent pest entry, ingress of water and other contaminants).
Interpretation	Maintenance of buildings The outside of buildings must be monitored and maintained in a condition such that they do not present a risk of product contamination. For example, pipework must be appropriately sealed to prevent pest entry, bird nesting sites must be eliminated (e.g. by using appropriate netting), and ingress of water and other contaminants must be prevented.

4.2 SITE SECURITY AND FOOD DEFENCE

Systems shall protect products, premises and brands from malicious actions while under the control of the site.

Interpretation

The objective is to ensure that the safety of finished products is not jeopardised through malicious actions, tampering or unauthorised persons gaining access to the site. Therefore, security systems must be in place to limit and control access to the external areas of the site, buildings and product. Where possible, the site should keep a record of all visitors to the site, including name, company, date, time of entry and exit, as well as the purpose of the visit.

The following clauses mirror those concerning food fraud (section 5.4), so the site can choose to consider the two topics (food defence and food fraud) together, if that is a more effective use of time and resource, or separately if the company prefers.

BRC Global Standards will publish additional guidance on food defence, which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

CLAUSE	REQUIREMENTS
4.2.1	The company shall undertake a documented risk assessment (threat assessment) of the potential risks to products from any deliberate attempt to inflict contamination or damage. This threat assessment shall include both internal and external threats.
	The output from this assessment shall be a documented threat assessment plan. This plan shall be kept under review to reflect changing circumstances and market intelligence. It shall be formally reviewed at least annually and whenever:
	 a new risk emerges (e.g. a new threat is publicised or identified) an incident occurs, where product security or food defence is implicated.
Interpretation	Documented assessment of security The company must undertake a threat assessment of the risks inherent to the operation with the objective of preventing malicious intervention. The threat assessment needs to consider both external threats (e.g. individuals or organisations gaining unauthorised access to the site, building or products) and internal threats, such as malicious tampering by staff who are authorised to be on site.
	Each area (e.g. warehouses, processing areas and external storage areas) needs to be assessed in terms of how vulnerable the product is to contamination. Sensitive or restricted areas, such as open product areas, are likely to be the most vulnerable; the vulnerability of the packaged product will depend on the nature of the packaging. Details of IT systems and data protection should also be included in the assessment.
	The output of the threat assessment must be a threat assessment plan, which details:
	 the identified risks the mitigation strategy; i.e. the steps or mechanisms used to avoid or mitigate the identified risks (see clauses 4.2.2 and 4.2.3).
	The threat assessment plan must be reviewed periodically; for example:
	 when there is a change to the site or buildings when new market intelligence indicates a new or changed threat following an incident where product security or food defence systems are implicated – this may include all forms of incident, as well as any customer complaints indicating that current food defence measures are not effective at least annually.
	Records of the review need to be available for the audit.
4.2.2	Where raw materials or products are identified as being at particular risk, the threat assessment plan shall include controls to mitigate these risks. Where prevention is not sufficient or possible, systems shall be in place to identify any tampering.

These controls shall be monitored, the results documented, and the controls reviewed at least annually.

CLAUSE

REQUIREMENTS

Interpretation

Additional controls to mitigate risks

The site's threat assessment plan may result in the need to take additional measures to mitigate risk to raw materials or product. This may include extra verification or testing when raw materials are delivered, or additional wrapping with tamper evidence on pallets. Whatever the measure, it should be appropriate and validated to ensure that it is effective.

The auditor will expect to see the documented plan (clause 4.2.1) and the methodology of determining which products, materials or areas require additional control. The additional measures and procedures should be documented and the auditor will expect to see these measures in action at the time of the audit.

Ideally the controls used should prevent the threat from occurring; however, where this is not possible, the controls should mitigate risk and use tamper evidence so that malicious activity can be seen and addressed in a timely manner, before it becomes a product safety issue.

The systems must be reviewed at least annually; i.e. every 12 months.

4.2.3

Areas where a significant risk is identified shall be defined, monitored and controlled. These shall include external storage and intake points for products and raw materials (including packaging).

Policies and systems shall be in place to ensure that only authorised personnel have access to production and storage areas, and that access to the site by employees, contractors and visitors is controlled. A visitor recording system shall be in place.

Staff shall be trained in site security procedures and food defence.

Interpretation

Authorised access

The basic requirement is that only authorised staff should have access to production and storage areas. Levels of access for various areas at the site may differ between employees.

Restriction of access to areas where sensitive materials are stored (e.g. laboratories, maintenance areas or document storage areas) should also be in place. Where appropriate, areas should be locked when not in use

To maintain site security, production and storage areas should have designated access points, which should be directly monitored or locked with, for example, keys issued to nominated personnel or key-code locks.

There must be a visitor-reporting or monitoring procedure. When visitors or contractors come on site they should not be able to enter production areas without first reporting to site representatives, who will make them aware of site rules and issue them with protective clothing.

All staff must be trained in the company security procedures and be part of the security arrangements. They should be encouraged to make enquiries on or report unknown persons in the facility. They must not compromise their personal safety; suspicious activities should always be referred to security staff (where they are available).

4.2.4

Where required by legislation, the site shall maintain appropriate registrations with the relevant authorities.

Interpretation

Registration of food production sites

In countries, states or territories where there is a legal requirement to register premises as food production sites, there must be documentary proof that the site has been appropriately registered; for example, this includes the requirement under EC Regulation No. 852/2004 on the Hygiene of Foodstuffs, Article 6(2).

This clause does not cover other legal registrations related to personnel, health and safety (such as fire regulations) or employment law, as these are outside the scope of the Standard.

4.3 LAYOUT, PRODUCT FLOW AND SEGREGATION

FUNDAMENTAL

The factory layout, flow of processes and movement of personnel shall be sufficient to prevent the risk of product contamination and to comply with relevant legislation.

Interpretation

The physical layout and flow of processes, materials and personnel must be identified, designed, managed and maintained to protect product integrity and prevent contamination, whether physical, chemical or microbiological.

CLAUSE	REQUIREMENTS
4.3.1	There shall be a map of the site. At a minimum, this map shall define:
	 access points for personnel access points for raw materials (including packaging), semi-finished products and open products routes of movement for personnel routes of movement for raw materials (including packaging) routes for the removal of waste routes for the movement of rework location of any staff facilities, including changing rooms, toilets, canteens and smoking areas production process flows.
Interpretation	Site map The aim of the site map is to provide an overview of all the locations within the site and the movements of products, material and people. It can then be used to support the site's risk assessments and subsequent prevention of contamination; for example, by identifying the locations where potential hazards (e.g. allergen cross-contamination) can occur.
	The site map will be expected to illustrate the locations of critical facilities and activities, as detailed in the requirement. If it is necessary to allow access through production areas, good practice is to identify designated walkways that ensure there is adequate separation from materials. Wherever possible, all facilities should be designed and positioned so that the movement of personnel is by simple, logical routes.
	It is often useful to put the required information on several overlapping maps rather than a single diagram. This is acceptable providing all the required information is clearly documented.
4.3.2	Contractors and visitors, including drivers, shall be made aware of all procedures for access to premises and the requirements of the areas they are visiting, with special reference to hazards and potential product contamination. Contractors working in product processing or storage areas shall be the responsibility of a nominated person.
Interpretation	Contractors and visitors Contractors and visitors (including drivers) must be made aware of all access restrictions and procedures related to them. Visitors should be told when they sign in and the information should be specific to the areas they will be visiting.
	Contractors who visit regularly should be trained to a similar level as employees, and a record of the training retained.
	Visitors and contractors working in product processing or storage areas should be monitored by a nominated person. All visitors must have someone on site who is responsible for overseeing their work and actions.
4.3.3	The movement of personnel, raw materials, packaging, rework and/or waste shall not compromise the safety of products. The process flow, together with the use of demonstrably effective procedures, shall be in place to minimise the risk of the contamination of raw materials, intermediate/semi-processed products, packaging and finished products.

CLAUSE REQUIREMENTS

Interpretation

Movement of personnel, raw materials, packaging, rework and waste

The HACCP or food safety plan must identify the potential risks associated with all production zones and the appropriate controls (including the level of prerequisite programmes) for the safe production of the products.

A combination of process flow and procedures (e.g. the prerequisite programme and work instructions) will be used to minimise risk to raw materials, packaging and products. Particular attention needs to be paid to the movement of personnel, raw materials, packaging, rework and waste, to ensure that the routes taken are defined and product safety is not compromised. For example, the removal of unnecessary packaging, such as debagging or removing outer boxes, should take place in a designated area, usually prior to transfer to production areas, in order to avoid potential foreign-body risks from discarded packaging.

The procedures developed to ensure product safety must be documented and validated as effective, and the appropriate staff must be trained. For example, where sites are receiving packaging through 'hole in the wall' operations, suitable controls should be in place to ensure that there is no risk to the product and the materials are treated appropriately. For example, an adjacent factory might deliver packaging materials on a conveyor or belt, as is often the case in dairy packing and carbonated beverages.

4.3.4

Premises shall allow sufficient working space and storage capacity to enable all operations to be carried out properly under safe hygienic conditions.

Interpretation

Work and storage space

Premises must be designed to allow sufficient working space and storage capacity so that all operations are carried out properly under safe, hygienic conditions, thereby reducing the potential for cross-contamination between activities because of close proximity. For example, overfull refrigerated storage may lead to doors being left open for extended lengths of time because of difficulties in accessing required materials. This would lead to a non-conformity.

Consideration should be given to all activities, including inspection, cleaning, pest control and maintenance, as well as manufacturing operations.

4.3.5

Temporary structures constructed during building work or refurbishment etc. shall be designed and located to avoid pest harbourage and ensure the safety and quality of products.

Interpretation

Temporary structures

Temporary structures (e.g. those constructed during building work or refurbishment) must be designed and located to avoid pest harbourage, unsanitary conditions and potential contamination of products. For example, where walls have to be knocked through during installation or expansion work, the integrity of the unit must be preserved to avoid pest entry, and scaffolding used in open product areas must be of the appropriate hygienic standard.

 $Risk \ assessment \ of \ temporary \ activities \ or \ structures \ should \ be \ completed \ prior \ to \ their \ introduction.$

4.4 BUILDING FABRIC, RAW MATERIAL HANDLING, PREPARATION, PROCESSING, PACKING AND STORAGE AREAS

The fabrication of the site, buildings and facilities shall be suitable for the intended purpose.

Interpretation

The design, construction and maintenance of the interior of the facility must support effective cleaning and protect products from contamination.

The type of finish to walls, floors and ceilings must, at a minimum, meet the requirements laid down in any applicable legislation for the industry, and be suitable for the intended purpose.

CLAUSE	REQUIREMENTS
4.4.1	Walls shall be finished and maintained to prevent the accumulation of dirt, minimise condensation and mould growth, and facilitate cleaning.
Interpretation	Walls This clause refers to the condition of the internal surfaces of the walls (other aspects of the wall's condition are covered separately in clause 4.1.3).
	The walls in areas handling raw materials and preparing, processing, packing or storing product must be kept in a sound condition and must be easy to clean and, where necessary, to disinfect. For example, walls must have a smooth, impervious finish with sealed surfaces, be in a good state of repair and be free from flaking paint.
	Tiling of walls is best avoided but, if present, must be in good condition, with no cracks or loose tiles. Ledges (e.g. from ducting or piping) should be kept to a minimum or designed to facilitate cleaning (e.g. with a slope to avoid dust collection).
	Vulnerable wall surfaces or corners (e.g. where vehicles pass in close proximity) should be protected from damage (e.g. with properly sealed metal plating or barriers). Junctions (including 'wall to floor', 'wall to ceiling' and 'wall to wall') should be maintained in good condition to facilitate cleaning (e.g. by being appropriately sealed).
4.4.2	Floors shall be suitably hard-wearing to meet the demands of the process, and withstand cleaning materials and methods. They shall be impervious, be maintained in good repair and facilitate cleaning.
Interpretation	Floors The floors in areas handling raw materials and preparing, processing, packing or storing product must be kept in a sound condition and be easy to clean and, where necessary, to disinfect. Floors must be constructed of materials that are impervious, hard-wearing, repairable and resistant to chemical attack so that they can withstand appropriate cleaning procedures.
4.4.3	Drainage, where provided, shall be sited, designed and maintained to minimise risk of product contamination and not compromise product safety. Machinery and piping shall be arranged so that, wherever feasible, process waste water goes directly to drain. Where significant amounts of water are used, or direct piping to drain is not feasible, floors shall have adequate falls to cope with the flow of any water or effluent towards suitable drainage.
Interpretation	Drainage Drainage must be designed and maintained to ensure that product contamination risks are minimised. For example, drainage design might include methods to prevent flow back and pest ingress, and routeing of waste systems to prevent dripping on products, packaging or ingredients.
	Due consideration must be given to drainage from any internal laboratories or other hazardous operations undertaken on site to ensure that blockages or the presence of micro-organisms could not result in the contamination of processing areas.
	Drainage systems must not constitute a potential risk to product (e.g. from potential leakage) when passing through or over production areas. Where feasible, the design of equipment must ensure that process waste water (e.g. condensate drainage from refrigeration or temperature-controlled areas, or sink waste water) goes directly to a drain to minimise contamination risk.

CLAUSE	REQUIREMENTS
	Where significant amounts of water are used (e.g. where wet cleaning is carried out) and direct piping to a drain is not possible, floors must have adequate falls to cope with the flow of effluent (i.e. pooling of water should not occur) as this constitutes a splash hazard and, therefore, a contamination risk.
	Note that the additional requirements for drainage in high-risk and high-care areas are covered in section 8.2.
4.4.4	Ceilings and overheads shall be constructed, finished and maintained to prevent the risk of product contamination.
Interpretation	Ceilings and overheads Ceilings and overheads in areas handling raw materials and preparing, processing, packing or storing product must be appropriately designed and kept in a sound condition to avoid the risk of contamination to product. Prevention of the accumulation of dirt, minimising condensation and mould growth, and facilitating cleaning should all be considered.
	In rooms with high ceilings that are difficult to clean or maintain, line covers over open product could reduce the risk of contamination.
	Mezzanine floors and suspended/elevated walkways in, for example, production areas or over production lines should be safeguarded to ensure they do not present a contamination risk to products below. Their design could include features such as solid treads, back plates and enclosed sides to prevent items from falling into the production areas. The cleaning methods for these floors and walkways should not allow waste materials or cleaning materials (e.g. wash water) to fall onto equipment or the production line below.
4.4.5	Where suspended ceilings or roof voids are present, adequate access to the void shall be provided to facilitate inspection for pest activity, unless the void is fully sealed.
Interpretation	Suspended ceilings Where suspended ceilings are used (or roof voids are present), access must be available for pest control purposes, even if this roof void is not normally used, unless it can be demonstrated that the void is entirely sealed.
	Refrigeration equipment is often located in the roof void, and access will be required for maintenance.
4.4.6	Where elevated walkways are adjacent to or pass over production lines, they shall be:
	 designed to prevent contamination of products and production lines easy to clean correctly maintained.
Interpretation	Elevated walkways Sites should include any elevated walkways in the procedures concerning installation and maintenance activities (including cleaning) with the express intention of ensuring that the walkways themselves (and their use) do not pose a hazard to the product. This is particularly important where open product is present. For example, the walkways should be:
	 constructed of a solid base and sides (rather than a perforated material) to make it less likely that material from footwear could fall off the walkway and onto the product or production lines below cleaned using minimal amounts of water to reduce the likelihood of splashing onto materials below included in the programme of documented inspections of the factory environment (see clause 3.4.4) to facilitate prompt corrective action in the event of a problem.
4.4.7	Where there is a risk to product, windows and roof glazing which are designed to be opened for ventilation purposes shall be adequately screened to prevent the ingress of pests.
Interpretation	Use of windows for ventilation Where there is a risk to product, such as in production or storage areas, windows and roof glazing that are designed to be opened for ventilation purposes must be adequately screened to prevent ingress of hazards such as pests or dust (e.g. by the use of mesh of an appropriate size to cover the windows).

CLAUSE	REQUIREMENTS
4.4.8	Doors (both internal and external) shall be maintained in good condition. At a minimum:
	 external doors and dock levellers shall be close fitting or adequately proofed external doors to open product areas shall not be opened during production periods except in emergencies where external doors to enclosed product areas are opened, suitable precautions shall be taken to prevent pest ingress.
Interpretation	Doors
	Doors and doorway equipment such as strip curtains must be in good condition, easy to clean and provide an adequate level of pest-proofing for the site. Doors and doorway equipment should be clean, maintained in good condition, and re-establish continuous contact with the floor when lowered.
	Doors through which vehicles (such as forklift trucks) travel should be inspected and door frames should be fitted with close-fitting metal plates for protection. External doors to open product areas where activities such as raw material handling, preparation, processing and packing occur must not be opened during production, except in emergencies.
	Where external doors to enclosed product areas are opened, suitable precautions must be taken to prevent pest ingress. Strip curtains are a common way of providing this protection; however, these must be adequately controlled to ensure effective proofing (i.e. they must not be damaged or missing, they must reach the floor and they must be used correctly).
	Sites should be aware that the doors themselves can be a source of physical contamination, particularly where they are designed to rise from floor contact to above the product as it is carried through (e.g. the potential for drip and therefore contamination of product as it passes through the doorway). It is not necessary to remove such doors, but sites should assess whether it is necessary to carry out mitigating steps, such as covering the product before it goes through the doorway.
	Mechanical and electronic doors should be included in any planned or condition-based maintenance programmes (i.e. they should be maintained and repaired in a timely fashion).
4.4.9	Suitable and sufficient lighting shall be provided for correct operation of processes, inspection of product and effective cleaning.
Interpretation	Lighting Adequate lighting must be provided to allow:
	 staff to be able to monitor quality and defects the correct operation of processes effective cleaning a safe working environment.
	Industry guidelines state that preparation, processing and packing areas should generally be illuminated to a minimum intensity of 200 lux, with inspection areas requiring higher illumination such as 500 or 750 lux. All areas need to be considered; for example, poor lighting in storage areas may hinder effective cleaning or inspection.
4.4.10	Adequate ventilation and extraction shall be provided in product storage and processing environments to prevent condensation or excessive dust.
Interpretation	Ventilation and extraction Adequate ventilation and extraction must be provided, particularly in areas where very dusty operations are carried out (e.g. in dry-ingredient handling areas) or where there is potential for condensation build-up (e.g. in cooking areas).
	Where air socks are used, the need for them to be cleaned and maintained should be considered. The frequency of this cleaning should be based on risk.

4.5 UTILITIES - WATER, ICE, AIR AND OTHER GASES

Utilities used within the production and storage areas shall be monitored to effectively control the risk of product contamination.

Interpretation

The utilities included within this requirement are specifically water, ice, air and other gases that need to be controlled to ensure they do not constitute a contamination risk to product. Other commonly considered utilities, such as electricity, natural gas or fuel, are not included within these requirements.

CLAUSE	REQUIREMENTS
4.5.1	All water (including ice and steam) used as a raw material in the manufacture of processed food, the preparation of product, hand-washing or for equipment or plant cleaning shall be supplied in sufficient quantity, be potable at point of use or pose no risk of contamination according to applicable legislation. The microbiological and chemical quality of water shall be analysed at least annually. The sampling points, scope of the test and frequency of analysis shall be based on risk, taking into account the source of the water, on-site storage and distribution facilities, previous sample history and usage.

Interpretation

Water supply

Water used must be provided in sufficient quantities (e.g. for cleaning operations), pose no contamination risk (e.g. be potable) and conform to relevant legislation by being suitably treated or drawn from mains supply. Where required by legislation, private water supplies and treatment plants should be approved by local or national authorities.

The frequency of water analysis must be based on risk, including:

- historical information
- the source of the water (e.g. mains supply or bore-hole)
- specific site concerns (e.g. duration of water storage or the use of lead pipes)
- treatments given to the water
- its usage.

The water is expected to comply with national legislation (e.g. EU directive 98/83/EC and its subsequent amendments) or, in the absence of this, with World Health Organization (WHO) standards for drinking water. The scope of testing completed by the site should be based on risk; for example:

- if the site has lead pipes, then tests should include the presence and concentration of lead
- if historical or published information indicates that the supply in the region has high levels of nitrate, then tests should incorporate this information.

Water quality tests must be completed at least annually and be based on a risk assessment. If the water is supplied by a water supply company, a chemical analysis from the water company will suffice for the chemical requirements, unless there are other risks identified in the delivery system (e.g. lead pipes). Alternatively, testing should be carried out at the site to ensure that the water is tested and approved at the point of use. Where water is extracted from bore-holes and/or sites have on-site treatment facilities, additional checks will be required to ensure that the water is not contaminated either at the bore-hole or during treatment and that the treatment remains effective. The water should be sampled at appropriate points of use and this should be documented in a sampling plan (see clause 4.5.2).

Where ice or steam is used in production or is in contact with food, it must be produced from potable water or pose no risk of contamination according to applicable legislation, and must be included within the sampling plan. Where legislation specifically allows the use of non-potable water (e.g. in the washing of raw fish or livestock), the water must meet all legislative requirements for that process. The site will also need to have established through the HACCP process that the water does not present a risk to the final products (e.g. by introduction of chemical contaminants) or to other products within the processing environment.

4.5.2

An up-to-date schematic diagram shall be available of the water distribution system on site, including holding tanks, water treatment and water recycling as appropriate. The diagram shall be used as a basis for water sampling and the management of water quality.

CLAUSE REQUIREMENTS

Interpretation

Water distribution

The aim of this requirement is to identify the key components of the water distribution system and how the components interconnect, particularly where potable and non-potable water are present. A fully detailed architect's diagram showing the complete pipework system is not required; a general plan, map or schematic diagram is sufficient. The plan should enable the site management and auditor to assess potential hazards in the distribution system and ensure that adequate management systems are in place to negate the hazards. For example, water-holding tanks may present a microbiological hazard if not covered; water pooling may occur if the water flow is not controlled; and where water is recycled (e.g. for can cooling), the water may need to be treated and sometimes filtered to ensure a satisfactory water quality.

Where the source of the water is a bore-hole or an on-site reservoir, the water treatment processes should be included on the water distribution plan. The best water sampling points to assess the quality of water should be deduced from this plan.

4.5.3

Air and other gases used as an ingredient or that are in direct contact with products shall be monitored to ensure this does not represent a contamination risk. Compressed air that is in direct contact with the product shall be filtered at point of use.

Interpretation

Monitoring of gases and steam

Compressed air, steam or gases used as an ingredient or directly in contact with food must be monitored to ensure they do not contaminate the product. The main risks to consider are: the carry-over of boiler water-treatment chemicals in steam; dust particles in compressed air; and oil used as a lubricant in compressed-air systems.

The level of monitoring needs to be based on an assessment of potential risk. Steam generated from potable water free from additives, for instance, is not likely to present a risk.

Compressed air in direct contact with products needs to be filtered prior to use and the filters checked and maintained to ensure they remain effective. The gauge of filtration (e.g. mesh size) and frequency of checks should be documented and based on risk assessment, taking into account the source of the air, the type of compressors used and the condition of the pipework (e.g. evidence of corrosion). The compressor suppliers or experts should be consulted to establish any potential risks and any necessary testing.

If gases are used, such as in modified atmosphere packing, they must be demonstrated as being of an appropriate quality. Usually such gases are supplied in a compressed form in metal cylinders and the supplier management process (approved suppliers and specifications, with certificates of conformance if required) would be sufficient. In these circumstances, the site would not be expected to undertake its own checks. Compressed gases are generally considered to be microbiologically safe and the Standard does not require routine testing of such gases unless a specific risk has been identified.

There may be additional risks where gases are produced on site and these would need to be evaluated through a risk assessment. Additional information can be obtained from the British Compressed Air Society (www.bcas.org.uk) and the European Industrial Gases Association (www.eiga.org).

4.6 EQUIPMENT

All food-processing equipment shall be suitable for the intended purpose and shall be used to minimise the risk of contamination of product.

Interpretation

Suitability of equipment for its intended purpose includes its condition so it does not pose a product contamination hazard; its ability to be effectively cleaned; and its capability of producing safe food products. Where equipment is stored, storage conditions must ensure the safety and integrity of the equipment so that it cannot become a source of contamination. For example, equipment should be stored clean and in such a way that it does not harbour pests.

Movable equipment should be restricted to use in designated areas; for example, forklift trucks and other items used in open product areas should not be used outside.

CLAUSE	REQUIREMENTS	
4.6.1	All equipment shall be constructed of appropriate materials. The design and placement of equipment shall ensure it can be effectively cleaned and maintained.	
Interpretation	Equipment design and construction Before new equipment is purchased, its intended use should be fully specified so that the equipment can be suitably designed and made of appropriate materials. This must include consideration of effective cleaning at appropriate frequencies (e.g. design for easy dismantling).	
	Documented evidence should be available to confirm commissioning prior to use (i.e. trials of operation, cleaning and maintenance). In order to facilitate routine cleaning, operation, inspection and servicing, equipment must be appropriately positioned (e.g. access provided under, inside and around it). Where equipment is permanently sited, it should be properly secured and sealed to the floor to prevent the accumulation of food debris underneath where it cannot be cleaned. It has been well documented that, where equipment or fixtures allow organic matter and/or pathogens to collect and survive, this can subsequently cause product contamination as pathogens such as <i>Salmonella</i> or <i>Listeria</i> can survive for prolonged periods in these conditions if left undisturbed.	
4.6.2	Equipment that is in direct contact with food shall be suitable for food contact and meet legal requirements where applicable.	

Interpretation

Equipment in direct contact with food

This requirement is designed to ensure that equipment is not a source of product contamination, and that it complies with relevant food contact legislation where such legislation exists (e.g. Food Contact Materials – Regulation (EC) 1935/2004 and its subsequent amendments).

In general, sites should use approved suppliers that are known to supply products designed for food use. New equipment should be purchased with a certificate of conformity or specification demonstrating that its food contact surfaces are suitable for food use. This may also be confirmed by labelling (such as the 'wineglass' and 'fork' symbols in the EU).

Issues have arisen through the purchase of equipment (especially plastic items) not designed for food use; for example, where plastic refuse bins have been used for ingredient storage. This can lead to the migration of chemicals into food products. Where evidence to confirm the suitability of food contact equipment is not available and the contact material is not a recognised food-safe material (such as stainless steel), a documented risk assessment should be carried out to justify its use and ensure that it is not a food safety risk. The risk assessment must consider factors such as:

- the nature of the food contact surface and its known characteristics
- the length of contact time with the food
- the nature of the food and its potential for contamination (e.g. fatty foods are often at increased risk from migration of contaminants from plastic materials).

The site should also consider the cleaning methods and chemicals used and their effects on the material's integrity. Further clarification should be sought where required (e.g. from the equipment manufacturer or cleaning chemical supplier, or from testing such as migration tests).

4.7 MAINTENANCE

An effective maintenance programme shall be in operation for plant and equipment to prevent contamination and reduce the potential for breakdowns.

Interpretation

To ensure that all equipment, including fixtures, fittings, cleaning tools and utensils, is suitably maintained and does not pose a product contamination risk, it must be controlled by a documented maintenance system. Planned maintenance may be completed internally or via contracted services. Maintenance undertaken internally must be documented (e.g. in the form of a plan or schedule) and records of the maintenance activity kept. For equipment that is maintained under external contracts, evidence of contractual agreements must be available.

CLAUSE	REQUIREMENTS		
4.7.1	There shall be a documented planned maintenance schedule or condition monitoring system which includes all plant and processing equipment. The maintenance requirements shall be defined when commissioning new equipment.		
Interpretation	Documented maintenance schedule There must be a documented planned maintenance schedule or condition monitoring system in place for all items of plant and processing equipment relevant to the production of food.		
	When commissioning new equipment and plant, a documented maintenance programme must be established. This should be based on risk assessment and information supplied by the equipment manufacturer or supplier (e.g. planned preventive maintenance, recommended maintenance checks and frequencies).		
4.7.2	In addition to any planned maintenance programme, where there is a risk of product contamination by foreign bodies arising from equipment damage, the equipment shall be inspected at predetermined intervals, the inspection results documented and appropriate action taken.		
Interpretation	Equipment inspection Where there is a risk of foreign bodies contaminating product due to wear or damage to equipment or pieces of machinery (e.g. sieves, mills, equipment covers etc.), there must be a periodic check of the equipment. A documented check procedure must be carried out at defined intervals (e.g. at process start-up, at start of shift, during product changeover, and after cleaning or maintenance).		
	Inspection results must be documented and, where appropriate, action taken.		
4.7.3	Where temporary repairs are made, these shall be documented and controlled to ensure that the safety or legality of products is not jeopardised. These temporary measures shall be permanently repaired as soon as practicable and within a defined timescale.		
Interpretation	Temporary repairs Temporary repairs must be suitable, kept to a minimum and used only in an emergency. They must be controlled (i.e. documented and notified to a shift leader) to ensure that the safety or legality of product is not jeopardised, and a system must be in place to demonstrate that a permanent repair is planned within a defined timescale (e.g. a works order).		
	The Standard is not prescriptive regarding the timescales for permanent repairs, as what is practicable will vary from site to site and according to the nature of the repair and any associated product safety risks. Typically, a full permanent repair is expected as soon as a replacement piece is available, or as soon as the line can be shut down. In all cases, the expectation is that the safety and legality of the product will be maintained in the interim.		
	In an organisation with a strong food safety culture, production staff should be knowledgeable about food safety, be empowered and feel ownership of compliance with the Standard so that they feel confident about informing the relevant individual or department when a repair or adjustment needs to be made.		

CLAUSE	REQUIREMENTS		
4.7.4	The site shall ensure that the safety or legality of products is not jeopardised during maintenance and subsequent cleaning operations. Maintenance work shall be followed by a documented hygiene clearance procedure.		
	Equipment and machinery shall be inspected by an authorised member of staff to confirm the removal of contamination hazards, before being accepted back into operation.		
Interpretation	Post-maintenance cleaning The site must ensure that the safety and legality of product is not jeopardised during maintenance and cleaning operations (e.g. equipment is not contaminated either by products used during the maintenance, such as sealants, nuts and bolts, or by machinery parts that have broken or disintegrated and have not been adequately removed).		
	Good practice is to schedule maintenance work outside production hours. Where this is not practical, suitable precautions must be taken to prevent the contamination of products, for example by removing the item to be maintained from the production area, or by using suitable screening to protect both the production line and any adjacent equipment or production lines.		
	A procedure must be in place to ensure that, following maintenance work, equipment is cleaned and inspected prior to use. An authorised member of staff (e.g. the production manager) is required to formally accept equipment back into operation following this inspection to confirm that maintenance and associated cleaning have been completed satisfactorily. Records need to be maintained (e.g. by signing the appropriate engineering record or line start-up check sheet) to demonstrate that the equipment has been inspected and is acceptable for use.		
4.7.5	Materials and parts used for equipment and plant maintenance shall be of an appropriate grade or quality.		
	Those materials (such as lubricating oil) that pose a risk by direct or indirect contact with raw materials (including primary packaging), intermediate products and finished products shall be food grade and of a known allergen status.		
Interpretation	Use of food-grade materials Materials used for equipment and plant maintenance that pose a risk of direct or indirect contact with raw material, intermediates or final product must be of food grade and the presence of any allergens must be known and managed accordingly. Documentary evidence of the food-grade status must be held (e.g. in a declaration by the supplier, on product data sheets or by demonstrable compliance to a recognised standard such as ISO 21469 for lubricants).		
4.7.6	Engineering workshops shall be kept clean and tidy, and controls shall be in place to prevent transfer of engineering debris to production or storage areas.		
Interpretation	Engineering workshops The engineering workshop must be controlled to minimise the potential for contamination of product. Consideration should be given to location and design, as well as procedures for control. For example, where it is not possible to avoid having an entrance directly from the engineering workshop to the production area, procedures must be in place to avoid contamination risks (e.g. by debris being carried inadvertently into the production or storage areas). These procedures may include changes of footwear and protective clothing, or matting specifically designed to collect any small pieces of debris from footwear (e.g. swarf mats). Workshops need to be kept clean and tidy, be operated in a controlled manner, and be included in the		
	housekeeping and cleaning procedures. The provision and location of hand-washing facilities for engineers entering the factory should be considered.		

4.8 STAFF FACILITIES

Staff facilities shall be sufficient to accommodate the required number of personnel, and shall be designed and operated to minimise the risk of product contamination. The facilities shall be maintained in good and clean condition.

Interpretation

This section focuses on staff facilities from the perspective of eliminating product contamination.

Appropriate staff facilities must be provided to enable staff to adhere to company policies (e.g. the correct storage of protective clothing and personal belongings) to ensure the risk of product contamination is kept to a minimum. This must include adequate facilities to accommodate staff fluctuations, such as high production times, seasonal variations or the use of agency staff.

Washing, changing and toilet facilities provided for visitors and contractors must be of a standard that allows non-staff members to meet suitable levels of hygiene. Best practice is that visitors and contractors follow exactly the same changing routine as staff (e.g. change in changing areas and not in management offices).

CLAUSE	REQUIREMENTS			
4.8.1	Designated changing facilities shall be provided for all personnel, whether staff, visitor or contractor. These shall be sited to allow direct access to the production, packing or storage areas without recourse to any external area. Where this is not possible, a risk assessment shall be carried out and procedures implemented accordingly (e.g. the provision of cleaning facilities for footwear).			
Interpretation	Changing facilities Designated changing facilities must be provided for all staff (including visitors and contractors). The location and position of facilities is an important consideration and this must be the subject of a risk assessment to ensure the protection of protective clothing from contamination before entering the production areas.			
	The size of the facilities needs to be adequate for the number of staff working at the factory and at times of peak staff numbers (e.g. at the start and end of shifts or when there are seasonal fluctuations).			
	Where changing facilities cannot be located with direct access to the production, packing or storage areas without recourse to an external area, a risk assessment must be used to identify where additional procedures need to be implemented (e.g. providing cleaning facilities for footwear where footwear is worn outside, or the donning of additional protective clothing on entry to production areas).			
4.8.2	Storage facilities of sufficient size to accommodate personal items shall be provided for all personnel who work in raw material handling, preparation, processing, packing and storage areas.			
Interpretation	Storage of personal items To prevent staff from bringing personal items (e.g. keys, mobile phones or coins) into production and storage areas where they could contaminate products (e.g. as foreign bodies), there must be sufficient and suitably secure storage for employees' belongings. Storage for bulky items such as motorbike leathers and helmets should be provided, as well as for smaller items such as jewellery and food.			
	Storage areas should be designed to facilitate good practice and cleaning (e.g. lockers with sloping tops to prevent the accumulation of rubbish and raised off the floor to facilitate cleaning).			
4.8.3	Outdoor clothing and other personal items shall be stored separately from production clothing within the changing facilities. Facilities shall be available to separate clean and dirty production clothing.			
Interpretation	Segregation of personal items from work clothing Separate storage facilities for personal items and work clothing are necessary to prevent cross- contamination of clothing via the locker. This can be achieved by:			
	 using a locker with a divider to separate work clothing from personal clothing enclosing protective clothing in a bag, such as a laundry bag, before use providing a separate area for the hanging of work clothing. 			
	Because of the potential for cross-contamination, clean protective clothing must be segregated from dirty protective clothing (e.g. through the provision of separate locker areas or a dedicated collection point for dirty laundry).			

CLAUSE Suitable and sufficient hand-washing facilities shall be provided at access to, and at other appropriate points within, production areas. Such hand-washing facilities shall provide, at a minimum: advisory signs to prompt hand-washing a sufficient quantity of water at a suitable temperature water taps with hands-free operation liquid/foam soap single-use towels or suitably designed and located air driers.

Interpretation

Hand-washing facilities

Dedicated hand-washing facilities must be provided at entrances to production areas and, where appropriate, at additional points within production areas. This is to ensure that hands are physically washed, rather than just sanitised, before starting work and as necessary during the working day. In some low-risk operations, the hand-wash prior to entry to the production area may be in a changing facility or toilet rather than within the entrance to the actual production area. In some dry environments where water is avoided, gel or alcohol sanitisers may be used in the production areas in place of hand-washing facilities, although staff will still be required to wash their hands before entering the production area.

The hand-washing facilities must be equipped with the following:

- appropriate instructions for use, considering the language needs of staff (e.g. including pictorial instructions)
- water in sufficient quantities and at a suitable temperature. The publication WHO Guidelines on Hand Hygiene in Health Care (recommended by Codex Alimentarius) highlights that warm water is more effective at cleaning than cooler water, with 40°C being demonstrably more effective than 20°C. It also notes that warm water is preferable to hot water because repeated exposure to hot water increases the risk of dermatitis (comfortably warm is generally considered to be about 45°C)
- taps that have hands-free operation (e.g. knee- or foot-operated taps or those with movement sensors)
- liquid or foam soap solution
- suitable hygienic hand-drying facilities (either single-use hand towels or suitably designed and located hand driers; roller towels are not acceptable as they are not single use). Where single-use towels are used, suitably designed and located bins should also be provided.

Good practice is that hand sanitiser is also provided at all hand-washing facilities. (Hand sanitiser is always required for high-risk and high-care operations – see clause 8.4.1.)

The provision and location of hand-wash basins are expected to follow industry best practice within that sector, including a risk assessment for breakage or damage. For some low-risk operations where hand-washing facilities are only provided within toilets before re-entering production, the requirements for hand-washing facilities will also apply to toilet areas.

4.8.5

Toilets shall be adequately segregated and shall not open directly into production or packing areas. Toilets shall be provided with hand-washing facilities comprising:

- basins with soap and water at a suitable temperature
- adequate hand-drying facilities
- advisory signs to prompt hand-washing.

Where hand-washing facilities within toilet facilities are the only facilities provided before re-entering production, the requirements of clause 4.8.4 shall apply and signs shall be in place to direct people to hand-washing facilities before entering production.

Interpretation

Toilets

Toilets must be adequately segregated from production areas and must not open directly into production or packing areas. There should be an intermediate ventilated space between the toilet cubicle and any production area to prevent foul odours from entering production areas.

The hand-washing facilities provided in toilets must be equipped with:

- appropriate instructions for use, considering the language needs of staff
- sufficient water at a suitable temperature (clause 4.8.4)
- soap (in any format)
- suitable hand-drying facilities (in any format).

CLAUSE	REQUIREMENTS			
	Where hand-washing facilities within toilet facilities are the only ones provided before re-entering production, the requirements of clause 4.8.4 apply, including suitable signage to direct staff to wash their hands prior to entering production areas.			
Where smoking is allowed under national law, designated controlled smoking areas share both isolated from production areas to an extent that ensures smoke cannot reach with sufficient extraction to the exterior of the building. Adequate arrangements for dea waste shall be provided at smoking facilities, both inside and at exterior locations. Electron to be permitted to be used or brought into production or storage areas.				
Interpretation	Smoking areas Facilities in line with national legislation must be provided for those staff wishing to smoke. These facilities must not be located within the packing or production areas where there is open food or ingredients, or where smoke could reach product or ingredients. Indoor facilities must have sufficient extraction to the exterior of the building.			
	Procedures for protective clothing and hand-washing must be in place whenever staff enter or leave production and packing areas (clause 7.4.1); therefore suitable facilities for staff to remove their protective clothing before smoking and for washing their hands afterwards must be provided. Signs must direct them to the hand-washing facilities.			
	There must be sufficient and appropriately positioned facilities for the waste generated by those persons smoking.			
	Where electronic cigarettes (e-cigs) are permitted on site, instructions for use must comply with national and local legislation. Electronic cigarettes must not be taken into storage, processing or production areas.			
4.8.7	All food brought into manufacturing premises by staff shall be appropriately stored in a clean and hygienic state. No food shall be taken into storage, processing or production areas. Where eating of food is allowed outside during breaks, this shall be in suitable designated areas with appropriate control of waste.			
Interpretation	Staff food Suitable storage facilities must be provided for food brought on site by staff, enabling it to be stored in a hygienic manner. Where refrigerators are provided for staff food, they should be kept clean, maintained and operated at an appropriate temperature. Refrigerators used for production materials and shelf-life samples must not be used for storing staff foodstuffs.			
	Food (including sweets and chewing gum) must not be taken into storage, processing or production areas, as it may constitute a risk to the product. Food must be adequately controlled when stored in other areas.			
	All food and drink must be consumed in designated areas away from food-handling, production and storage areas. Where appropriate, designated outside areas can be provided for staff to eat food; where provided, these must have an appropriate control of waste.			
	Drinking of water from purpose-made dispensers by using disposable conical cups or spill-proof containers may be allowed, provided it is confined to a designated area, minimising the risk to product, and suitable disposal facilities are provided.			
4.8.8	Where catering facilities (including vending machines) are provided on the premises, they shall be suitably controlled to prevent contamination of products (e.g. as a source of food poisoning or introduction of allergenic material to the site).			
Interpretation	Catering facilities Where the company provides a canteen or other food service (including food vending services) for members of staff, the kitchens and cold-storage areas need to be suitably controlled to prevent the contamination of products (e.g. by microbiological or allergen contamination).			

In the absence of specific legislative requirements and assessments for the control of hazards in catering facilities, a study based on HACCP principles should have been carried out on any catering facilities

should be part of the site's own internal audit or hygiene inspection programme.

provided for the staff. The risks identified should be effectively controlled; in particular, those associated with staff hygiene, cleaning, cross-contamination between raw and cooked foods, and storage conditions. At the BRC Global Standards audit, there will be a basic inspection of the kitchen facilities. Catering facilities

REQUIREMENTS

In some operations (e.g. sites manufacturing a product with an allergen claim), specific allergens present a particular risk. These sites should specify any relevant company policies to confectionery vending suppliers and catering facilities (e.g. a 'no nut policy' on site because of the manufacture of 'nut-free' products).

4.9 CHEMICAL AND PHYSICAL PRODUCT CONTAMINATION CONTROL: RAW MATERIAL HANDLING, PREPARATION, PROCESSING, PACKING AND STORAGE AREAS

Appropriate facilities and procedures shall be in place to control the risk of chemical or physical contamination of product.

Interpretation

The risk of foreign-body and chemical contamination must be minimised through the consideration of potential sources and the implementation of control procedures within the HACCP or food safety plan. Areas to consider include storage, processing, equipment, maintenance, building structures, cleaning operations and personnel.

Staff facilities and communal areas such as entrance corridors also need to be considered to ensure that their design and the processes carried out within them do not pose a risk to products (e.g. the presence of staples or drawing pins on open noticeboards). Regular documented inspections (clause 3.4.4) must be carried out to verify that these controls are in place.

4.9.1 CHEMICAL CONTROL

 4.9.1.1 Processes shall be in place to manage the use, storage and handling of non-food chemicals to prevent chemical contamination. These shall include, at a minimum: an approved list of chemicals for purchase availability of material safety data sheets and specifications confirmation of suitability for use in a food-processing environment avoidance of strongly scented products the labelling and/or identification of containers of chemicals at all times a designated storage area with restricted access to authorised personnel 	CLAUSE	REQUIREMENTS		
 availability of material safety data sheets and specifications confirmation of suitability for use in a food-processing environment avoidance of strongly scented products the labelling and/or identification of containers of chemicals at all times a designated storage area with restricted access to authorised personnel 	4.9.1.1			
use by trained personnel only.		 availability of material safety data sheets and specifications confirmation of suitability for use in a food-processing environment avoidance of strongly scented products the labelling and/or identification of containers of chemicals at all times 		

Interpretation

Storage and handling of non-food chemicals

Non-food chemicals present a potential product contamination or taint risk if they are not stored and handled correctly. The site needs to demonstrate controls on non-food chemicals, including the following:

- an approved list of chemicals for purchase this is to prevent inappropriate chemicals from being purchased. This applies to all cleaning chemicals, pesticides and other chemicals which may be used in the production environment
- material safety data sheets and specifications provided by the supplier. These should be up-to-date and accurate
- confirmation that the chemicals are suitable for use in a food-processing area (i.e. they are non-tainting and not highly toxic). For example, cleaning chemicals must be selected to avoid the risk of product tainting (chemicals such as phenolics and those that are strongly scented are not suitable)
- avoidance of strong-scented products
- identification of chemicals (e.g. labelling of all containers) at all times, to minimise the potential for inadvertent use
- designated storage with restricted access limited to authorised personnel. Potentially harmful chemicals
 (e.g. sodium hypochlorite) must be suitably stored to prevent inadvertent product contamination. Good
 practice is to provide bunded areas around appropriate chemical and oil tanks and to ensure that
 safe-use/storage instructions from the manufacturer are implemented (e.g. store acid and alkaline
 materials away from each other and store powders above liquids in case of spillage and subsequent
 reaction). Good practice also includes supplying cleaning chemicals to production areas ready diluted
 (for use with verified auto-dosing systems) and to ensure that stocks of cleaning chemicals not required
 for the current production or cleaning activity are stored away from the production area
- use of chemicals by trained personnel only, as evidenced by training records.

CLAUSE **REQUIREMENTS** Chemicals that are likely to come into direct contact with foods when used as intended (e.g. materials such as oils or lubricants used on machinery), as well as terminal sanitisers that are designed to be used without rinsing with water, should be confirmed as suitable for food use. (This would not include general detergents and cleaning materials, as these should not come into direct contact with food.) Consideration may need to be given to the legislative requirements of specific countries, states or territories. For example, legislation may require that materials do not contain toxic or prohibited substances, that lubricants are suitable for food use or that terminal sanitisers meet applicable standards (e.g. the Biocidal Products Regulation (EU) No. 528/2012). Where strongly scented or taint-forming materials have to be used, for instance for building work, 4.9.1.2

procedures shall be in place to prevent the risk of taint contamination of products.

Interpretation

Strong scents and taints

manage these hazards.

Wherever possible, strongly scented or taint-forming materials must not be used. However, where these are necessary (e.g. for some building work), procedures must be in place to avoid the risk of taint contamination of products. For example, relevant information must be requested from contractors, detailing the chemicals to be used and the controls (such as the extraction of fumes) that will need to be in place. A risk assessment of the information should be completed prior to commencement of the work.

4.9.2 METAL CONTROL

CLAUSE	REQUIREMENTS			
4.9.2.1	There shall be a documented policy for the controlled use and storage of sharp metal implements including knives, cutting blades on equipment, needles and wires. This shall include a record of inspection for damage and the investigation of any lost items. Snap-off blade knives shall not be used.			
Interpretation	Sharp metal implements Where sharp metals such as knives, needles or cheese wires are used, there must be a documented policy. This will outline:			
	 the controls in place inspection and breakage/loss reporting procedures storage when not in use other controls, such as the numbering of knives or the use of issue and return logs. 			
	The company should aim to ensure that shards of missing metal are located and that the source of any loose metal is identified.			
	Snap-off blades (i.e. where the old segment of blade can be snapped off to reveal a new sharp edge) are a source of potential metal contamination and are not permitted in any area of production or storage. Other metal items, such as non-production blades, engineering tools and equipment, must be stored away from production areas to minimise their potential for contaminating product. For example, spanners used for adjusting machinery should not be left out, but should have a designated place for storage, such as a locked toolbox fixed to a wall.			
4.9.2.2	The purchase of ingredients and packaging which use staples or other foreign-body hazards as part of the packaging materials shall be avoided.			
	Staples, paper clips and drawing pins shall not be used in open product areas.			
	Where staples or other items are present as packaging materials or closures, appropriate precautions shall be taken to minimise the risk of product contamination.			
Interpretation	Staples, paper clips and similar metallic items Staples are often used in packaging. However, their use needs to be considered, since they are a potential source of contamination and the purchase of ingredients or packaging materials containing them must be avoided. Where ingredients with potential foreign bodies cannot be avoided, there need to be controls to			

Staples, paper clips and drawing pins (i.e. thumb tacks or pin tacks) must not be used in open product areas.

4.9.3 GLASS, BRITTLE PLASTIC, CERAMICS AND SIMILAR MATERIALS

4.9.3 GLASS, BRIT	TLE PLASTIC, CERAMICS AND SIMILAR MATERIALS
CLAUSE	REQUIREMENTS
4.9.3.1	Glass or other brittle materials shall be excluded or protected against breakage in areas where open products are handled or there is a risk of product contamination.
Interpretation	Exclusion of unnecessary materials The company must undertake an assessment of glass and other brittle items in open product areas and areas where there is a risk of contamination of product or packaging and, wherever possible, remove these items. Where it is not possible to remove all items, they must be protected against breakage (e.g. by the use of adhesive plastic sheeting, reinforcement or shielding) and included on a register for inspection purposes (clause 4.9.3.2). This clearly does not apply to glass or brittle materials used to pack final products, which are covered separately in section 4.9.4.
4.9.3.2	Procedures for handling glass and other brittle materials (other than product packaging) shall be in place where open products are handled or there is a risk of product contamination. These procedures shall include, at a minimum:
	 a list of items detailing location, number, type and condition recorded checks of the condition of items, carried out at a specified frequency that is based on the level of risk to the product details on cleaning or replacing items to minimise the potential for product contamination.
Interpretation	Documented handling procedures Procedures for handling glass and similar materials (other than packaging which is covered in section 4.9.4) need to be documented to ensure that the risks of product contamination are managed.
	The documentation must include:
	 a list or register of items, detailing their location, number, type and condition. When creating the list, it is important to be realistic; the objective is to remove brittle items where possible and create a list of items for inspection which present a real risk of breakage and contamination of products (i.e. those that are in open product areas or where risk assessment shows there is a genuine risk to product). (The list could also detail the frequency with which the items must be checked.) recorded, routine inspections to verify the condition of these items. Inspections must be carried out at a
	 specified frequency based on risk assessment; some areas may be checked more frequently than others because of their potential to form a foreign-body hazard in the product. (A record of the inspection must be maintained even when there is no change in the condition of the inspected items
	 the procedures that allow cleaning or replacement of items in a way that minimises potential risk to products (e.g. replacing bulbs in fly-killing devices).
Example	A factory identifies part of the production line which has plastic-laminated line covers that may chip or break. The condition of this section of the line is specifically checked on a daily basis prior to production, because it is above open food and any breakage or damage is likely to result in a foreign-body issue. The same factory has a brittle plastic dial cover on a control panel on the exterior of a piece of equipment not close to open product. This is checked only monthly, as a break and subsequent foreign-body issue is unlikely to arise.
Further guidance	Developing an effective glass control programme The aim of this requirement is to protect consumers from a potentially serious physical hazard by the removal of harmful items, and to develop a comprehensive list of items that should be routinely inspected to minimise the risk of any damage or breakage going undetected.
	To start with, carry out an assessment of the glass and brittle plastic items in open product areas and, wherever possible, remove them (see clause 4.9.3.1). If the item cannot be removed, it must be protected against breakage (e.g. with adhesive sheets or reinforcements) and included on a register for inspection purposes.

CLAUSE REQUIREMENTS

When creating a list of items for inspection, it is important to be realistic. The objective is to create a list of items that represent a real risk of breakage and product contamination. For example, the window above the production line is likely to be high-risk, as any breakage is likely to contaminate the product. But the window in the MD's office, on the other side of the site, does not need to be included unless there is a genuine risk of product contamination if the window breaks.

The frequency of the inspections must be based on risk assessment. The quality of the risk assessment is important as some items will probably be checked infrequently because of their lower risk status, whereas others may require frequent checks because of their prominent location and associated risk. For example, checking the window above the production line is likely to form part of the daily line start-up procedures.

You must ensure you have a contingency procedure in place that allows the reporting and timely management of any breakage (i.e. if an item is found to be damaged or broken during an inspection or if an item breaks during use).

There are a number of risk assessment techniques that can be used within food sites and the Standard is not prescriptive about which should be selected. However, there are two key considerations in relation to glass and brittle materials:

- the potential for damage or breakage
- the location and consequently the likelihood of a broken fragment contaminating a food product.

The importance of good documentation and record-keeping

Five key documents are required:

- a list of items giving details of their location, number, type and condition
- a risk assessment defining the required frequency of checks
- records of the routine inspections to verify the condition of these items (an example checklist is shown below)
- procedures that allow the cleaning or replacement of items in a way that minimises potential risk to products
- a procedure for the management of any breakages (see clause 4.9.3.3).

A record of the checks must be maintained even when there is no change to the status of the item. This is to demonstrate that the checks were made, so that in the event of a breakage you can be confident that the item was intact at the previous scheduled inspection, allowing any investigation or action to focus on a defined time period.

Examples

ITEM	LOCATION	NUMBER	ТУРЕ	CONDITION	FREQUENCY OF INSPECTION (REFER TO RISK ASSESSMENT FOR FULL DETAILS)
Windows	Production	6	Glass	Fully intact Protected using adhesive sheeting	Monthly
Protective Guard	On production line 1	1	Rigid Plastic	Fully intact	Daily (NB Recorded on line start up records)

Example of a glass register

MONTHLY GLASS CHECK			
Month:	Date Checked:		
Checked By:			

AREA/ITEM	DAMAGED OR MISSING (Y/N)	COMMENTS/ACTIONS

Example of a glass/brittle plastic check record

AREA/ ITEM	DAMAGED OR MISSING (Y/N)	COMMENTS/ ACTIONS	DATE	CHECKED BY

An alternative glass check record, where different individuals perform checks on different dates

4.9.3.3

Procedures detailing the action to be taken in case of breakage of glass or other brittle items shall be implemented and include the following:

- training of staff in the correct procedure
- quarantining the products and production area that were potentially affected
- cleaning the production area
- inspecting the production area and authorising production to continue
- changing of workwear and inspection of footwear
- specifying those staff authorised to carry out the above points
- recording the breakage incident
- safely disposing of contaminated product.

Interpretation

Breakage procedures

There must be documented procedures detailing the course of action to be taken when a breakage of a glass, brittle or hard plastic material, ceramic or similar item occurs. This must be based on risk assessment (therefore, the action taken may depend on the area in which the breakage occurred) and should include:

- who has been trained to clear up broken items safely while minimising risks to product safety
- isolation, inspection and management (e.g. product disposal) of potentially contaminated product (raw materials, packaging, final product etc.)
- isolation of potentially contaminated area (e.g. specifying a 10-m exclusion zone)

CLAUSE **REQUIREMENTS** how to clear up the broken item, including any designated equipment such as a brush, shovel and bin • how to clean the area and which cleaning equipment to use – this is important to ensure that glass particles are not transferred on equipment from one area to another how to dispose of debris • inspection of the production area after cleaning, and the authorisation to recommence production • changing of production clothing (staff and cleaners) • inspection of footwear (staff and cleaners) records to keep • identification of authorised staff to complete each of the above actions. The site should consider how to remove broken items, particularly larger items, from the premises. A designated, authorised contractor may be required. **Further** Typical steps to take in the event of a glass breakage In the event of a breakage, the following procedure must be followed: quidance • Notify a responsible person. (The site must identify the supervisors, line managers or production managers who should be notified and they should have sufficient knowledge and authority to take Where the breakage occurs near open product (e.g. near a production line), production in the area should be stopped. • Isolate the area of the breakage to ensure glass is not inadvertently distributed to other areas. Discard products in the area that are contaminated or likely to be contaminated. If the break is discovered during a routine inspection, it will be necessary to consider all the products that have been manufactured since the last satisfactory inspection and the possibility that these may be contaminated. • Carefully clear the broken glass. The site should have specific cleaning equipment. Once the area has been cleaned, it should be inspected and signed off before production resumes. • A record of all breakages should be maintained. 4.9.3.4 Where they pose a risk to product, glass windows shall be protected against breakage. Interpretation Protection of windows against breakage Where it has been assessed that glass windows (including glazing in walls) pose a risk to product (e.g. where they are in close proximity to production or storage areas), they must be protected against breakage. This could be achieved by the use of adhesive plastic sheeting. Where they pose a risk to product, bulbs and strip lights (including those on electric fly-killer devices) shall 4.9.3.5 be adequately protected. Where full protection cannot be provided, alternative management such as wire-mesh screens or monitoring procedures shall be in place. Interpretation Protection of lights against breakage The site must assess where light bulbs and strip lights pose a risk to product (e.g. where they are in close proximity to production, storage areas or staff facilities). Where a risk is identified, light bulbs and strip lights must be protected against breakage. All types of lighting must be considered in order to minimise the likelihood of breakage and the spread of glass shards. Depending on the type of lighting used, protection can normally be achieved through the appropriate use of shatterproof light tubes, plastic sleeving or diffusion covers. Where full protection cannot be achieved, alternative methods of management, such as wire-mesh screens or monitoring procedures, must be in place. **Quick tips** Ensure that all non-essential brittle materials are removed from open product areas (clause 4.9.3.1). • Ensure that the list of glass and brittle items is complete and contains all relevant items (i.e. those that are located in open product areas or have the potential to contaminate products). • Ensure that glass checks are completed at the predefined frequency.

4.9.4 PRODUCTS PACKED INTO GLASS OR OTHER BRITTLE CONTAINERS

Interpretation

Where products are packed into glass or other brittle materials (e.g. ceramic pots), the risk of breakage is increased and the packaging materials themselves present a significant foreign-body risk. These requirements deal specifically with the additional controls required to reduce the risk of contamination. They do not apply where products are not packed into glass or similar brittle containers.

CLAUSE	REQUIREMENTS	
4.9.4.1	The storage of the containers shall be segregated from the storage of raw materials, product or other packaging.	
Interpretation	Storage There must be dedicated, segregated storage for containers. Ideally a separate storage room should be used for storage of empty containers. Where the containers are in a shared warehouse, a distinctly separate area must be used. Warehouse product flow must be considered to reduce the risk of broken glass or fragments being carried into raw material storage areas.	
4.9.4.2	Systems shall be in place to manage container breakages between the container cleaning/inspection point and container closure. This shall include, at a minimum, documented instructions which ensure:	
Interpretation	 the removal and disposal of at-risk products in the vicinity of the breakage; this may be specific for different equipment or areas of the production line the effective cleaning of the line or equipment which may be contaminated by fragments of the container; cleaning shall not result in the further dispersal of fragments, for instance by the use of high-pressure water or air the use of dedicated, clearly identifiable cleaning equipment (e.g. colour-coded) for removal of container breakages; such equipment shall be stored separately from other cleaning equipment the use of dedicated, accessible, lidded waste containers for the collection of damaged containers and fragments a documented inspection of production equipment is undertaken following the cleaning of a breakage to ensure cleaning has effectively removed any risk of further contamination authorisation is given for production to restart following cleaning the area around the line is kept clear of broken glass. Breakages The documented instructions for dealing with breakages must cover those points listed in the requirement. However, where high-speed filling lines are used with automatic breakage detection and cleaning systems,	
	not all these practices will be practical. In such cases, the site must be able to demonstrate that the system is capable of consistently and safely removing glass fragments, and that factors such as low water pressure which may affect the performance of the acceptance and/or rejection of implicated products are understood, documented and controlled.	
4.9.4.3	Records shall be maintained of all container breakages on the line. Where no breakages have occurred during a production period, this shall also be recorded. This record shall be reviewed to identify trends and potential line or container improvements.	
Interpretation	Records All breakages must be recorded. This record should include:	
	 the location where the breakage occurred a record of the action taken sign-off by an authorised member of staff, e.g. a shift leader, production manager or quality assurance representative, who is trained and competent. 	
	Where no breakages have occurred during a production period, this must also be recorded. The records must be periodically reviewed to identify trends – for example, during the management review of incidents (clause 1.1.4).	

4.9.5 WOOD

CLAUSE	REQUIREMENTS	
4.9.5.1	Wood should not be used in open product areas except where this is a process requirement (e.g. maturation of products in wood). Where the use of wood cannot be avoided, the condition of wood shall be continually monitored to ensure it is in good condition and free from damage or splinters which could contaminate products.	
Interpretation	Wood in open product areas The use of wood is not permitted in production areas except where it is a requirement of the process (e.g. wooden casks used for some alcoholic beverages, or wooden crates for incoming raw materials in fresh produce packhouses). Therefore items such as wooden pallets should not be present in open product areas.	
	Where wood cannot be avoided, a procedure must be in place to:	
	 ensure the use of wood is covered by the HACCP risk assessment identify damaged items minimise the potential for contamination ensure that the wood is continually monitored (e.g. by regular checks to ensure it is in good condition and clean). 	

4.9.6 OTHER PHYSICAL CONTAMINANTS

CLAUSE		REQUIREMENTS
4.9.6.1	Procedures shall be in place to prevent physical contamination of raw materials by raw material packaging (e.g. during debagging and deboxing procedures to remove the packaging).	
Interpretation	on	Raw material packaging Prior to packaged raw materials being taken into open product or processing areas, the packaging should be visually checked for any potential sources of contamination, and cleaned if necessary.
		Where packaging is removed from raw materials prior to use, documented procedures should be in place so that the person carrying out the activity knows how to do so without creating a contamination hazard to the raw material.
4.9.6.2		Pens used in open product areas shall be controlled to minimise the risk of physical contamination (e.g. designed without small parts and detectable by foreign-body detection equipment).
Interpretation	on	Control of pens The type of control applied to pens will depend on the nature of the process, the site and the potential for contamination should those pens be lost or damaged in the production or storage area. In some cases, the purchase of metal-detectable pens is sufficient, whereas in others, the purchase of pens is restricted to those with no small parts so that any breakage does not result in small pieces of undetectable plastic in product.

4.10 FOREIGN-BODY DETECTION AND REMOVAL EQUIPMENT

The risk of product contamination shall be reduced or eliminated by the effective use of equipment to remove or detect foreign bodies.

Interpretation

The risk of foreign-body contamination must be minimised using food industry best practice, such as X-ray inspection, metal detection, sieves, magnets or scanner technology.

BRC Global Standards has produced a guideline to foreign-body detection which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

4.10.1 SELECTION AND OPERATION OF FOREIGN-BODY DETECTION AND REMOVAL EQUIPMENT

CLAUSE	REQUIREMENTS	
4.10.1.1	A documented assessment in association with the HACCP study shall be carried out on each production process to identify the potential use of equipment to detect or remove foreign-body contamination. Typical equipment to be considered may include:	
	 filters sieves metal detection magnets optical sorting equipment X-ray detection equipment other physical separation equipment (e.g. gravity separation, fluid bed technology). 	
Interpretation	Documented assessment The HACCP analysis should be the starting point for implementing an effective foreign-body control programme. Potential hazards and their sources must be identified so that appropriate control procedures can be put in place to minimise the likelihood of product contamination.	
4.10.1.2	The type, location and sensitivity of the detection and/or removal method shall be specified as part of the site's documented system. Industry best practice shall be applied with regard to the nature of the ingredient, material, product and/or the packed product. The location of the equipment or any other factors influencing the sensitivity of the equipment shall be validated and justified.	
Interpretation	Type, location and sensitivity The choice of location for foreign-body detection equipment is vital for its effective use. Equipment should be placed as close to the end of the production process as is practical, so that the whole process (including packing lines) is protected.	
	When selecting equipment and determining the best location for it, the potential environmental effects (e.g. temperature, moisture or speed of line) should be considered and discussed with the equipment supplier.	
	The sensitivity of detectors must be specified and best practice applied, taking into account the nature of the food, contamination characteristics, and the location and aperture size of the detector. For example, it is likely that metal detectors will be sensitive to ferrous, non-ferrous and stainless steel test pieces, using test sizes according to industry best practice for the particular product type or customer requirements. Good practice is for foreign-body detectors to have adequate security settings so that only authorised personnel can alter them.	
	The Standard expects the detector and its location to be validated at set-up; for example, by adjusting the machine's sensitivity using a range of typical products to establish the most sensitive practical setting which gives rise to consistent rejection without false rejects.	
	The established settings must be recorded and verified through regular checks of the equipment; these checks are generally undertaken using test pieces of a size just above the limit of detection.	

CLAUSE **REQUIREMENTS** The site shall ensure that the frequency of the testing of the foreign-body detection and/or removal 4.10.1.3 equipment is defined and takes into consideration: • specific customer requirements • the site's ability to identify, hold and prevent the release of any affected materials, should the equipment fail. The site shall establish and implement corrective action and reporting procedures in the event of a failure of the foreign-body detector and/or removal equipment. Action shall include a combination of isolation, quarantining and re-inspection of all products produced since the last successful test or inspection. Interpretation System monitoring and corrective action The frequency of testing the monitoring equipment must be defined in procedures. The frequency of routine tests should consider: • the need for additional checks at start-up and finish of shifts product changeovers • the need for regular checks throughout production (hourly testing is expected for many detection systems) • changes in machine settings or following downtime • any specific customer requirements • the site's ability to recover and retest product in the event of a failure. In the event that equipment is discovered not to be working, all of the product that has passed through the detector since it was last verified to be working should be rechecked. There must be procedures in place specifying the action required in the event of the detector failing a routine test (e.g. failing to detect or reject a test piece). The people responsible for completing the tests must also be trained in this procedure (clause 7.1.1). The procedures must include a combination of isolation, quarantining and re-inspection of all product produced since the last successful test. If the cause of the failure is a system fault, the fault should be repaired before recommencing production on the implicated line. Where foreign material is detected or removed by the equipment, the source of any unexpected material 4.10.1.4 shall be investigated. Information on rejected materials shall be used to identify trends and, where possible, instigate preventive action to reduce the occurrence of contamination by the foreign material. Interpretation Investigation of rejected material Products rejected or retained by detection systems can provide valuable information about possible problems arising from raw materials or the production process, and an early warning of potential issues. Rejected products should therefore be examined to identify the cause of rejection. Identified causes should be investigated and recorded. The data on rejected and retained product must also be used as the basis for analysing trends. This trend analysis may be used to establish preventive actions to reduce future contamination. Information about false rejects should also be recorded, because this may suggest an error with the detector or indicate that the settings are too sensitive for a particular product and require adjustment.

4.10.2 FILTERS AND SIEVES

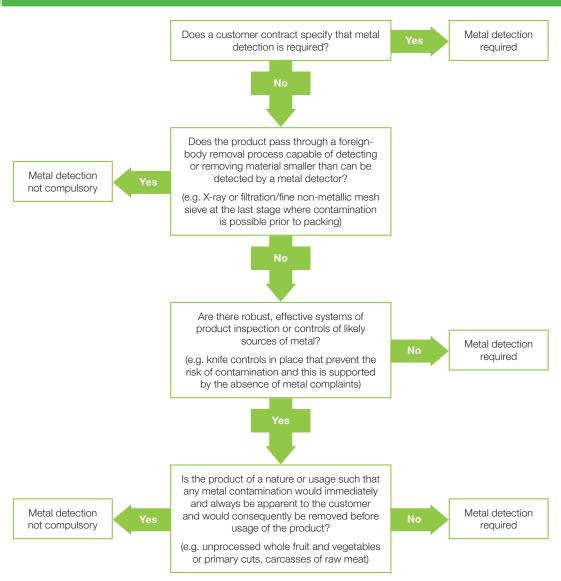

CLAUSE	REQUIREMENTS
4.10.2.1	Filters and sieves used for foreign-body control shall be of a specified mesh size or gauge and designed to provide the maximum practical protection for the product.
Interpretation	Mesh and gauge size To ensure the system provides maximum protection, consideration must be given to mesh and gauge size. The smallest practical size should be used.
	The size will be documented and details made easily available to staff using the equipment.
4.10.2.2	Filters and sieves shall be regularly inspected or tested for damage at a documented frequency based on risk. Records shall be maintained of the checks. Where defective filters or sieves are identified this shall be recorded and the potential for contamination of products investigated and appropriate action taken.
Interpretation	Routine inspection Filters and sieves must be monitored to ensure they themselves do not pose a foreign-body hazard and are working effectively. There must be a documented procedure which includes the frequency of checks, responsibilities, and action to be taken when issues are identified. The frequency of checks should be based on the nature of the sieve (e.g. a perforated-drum sieve is less likely to fail than a wire-mesh sieve), historical evidence of performance, and risk to finished product. It would be difficult to justify an inspection frequency of less than once per week. The results of sieve monitoring must be recorded.
	The material from which sieves and filters are manufactured should be considered, to minimise the potential for breakages that lead to foreign-body issues (e.g. where sieves or filters are used as part of a justification for not requiring metal detection, they should be made of non-metallic mesh).
	Where defective filters or sieves are identified, this must be recorded, the potential for contamination of products investigated, and appropriate action taken.

4.10.3 METAL DETECTORS AND X-RAY EQUIPMENT

CLAUSE	REQUIREMENTS
4.10.3.1	Metal detection equipment shall be in place unless risk assessment demonstrates that this does not improve the protection of final products from metal contamination. Where metal detectors are not used justification shall be documented. The absence of metal detection would only normally be based on the use of an alternative, more effective method of protection (e.g. use of X-ray, fine sieves or filtration of products).
Interpretation	Requirement for metal detection The Standard presumes that metal detection provides improved protection for customers and should form part of the food protection system of a site. Its absence would normally only be based on the use of an alternative, more effective, method of protection (e.g. the use of X-ray, fine sieves or filtration). There will, however, be situations where metal detection does not, on the basis of risk assessment, provide any significant additional protection to the consumer.
	Where metal detectors are not used, a risk assessment must be available to justify the reasons why. While complaint levels are a factor in making a decision on the necessity for a metal detector, this evidence alone will not be sufficient justification for not using one. (For example, there may be instances of contamination which have not been reported by consumers.) Any justification for the absence of metal detection should be based on the nature of the product, the risk to the consumer, and alternative controls in place at the site which prevent metal contamination. Cost alone is not sufficient reason.
	In all circumstances where products are manufactured to a customer's specification, sites must comply with any customer requirement for metal detection of their products. The decision tree provides further guidance on the need for metal detection equipment for products not packed into metallic containers.
	Where the product is packed into metal packaging, an effective alternative test method must be developed (e.g. X-ray or metal-detecting the product at the stage prior to packing, or the use of magnets and product inspection).
	Failsafes or alarms should be implemented to notify production staff when failure of equipment is likely. It is vital to know when equipment designed to remove contaminated product is not functioning.

CLAUSE REQUIREMENTS

Further guidance

Decision tree for metal detection

4.10.3.2

The metal detector or X-ray equipment shall incorporate one of the following:

- an automatic rejection device, for continuous in-line systems, which shall either divert contaminated product out of the product flow or to a secure unit accessible only to authorised personnel
- a belt stop system with an alarm where the product cannot be automatically rejected (e.g. for very large packs)
- in-line detectors which identify the location of the contaminant to allow effective segregation of the affected product.

Interpretation

Rejection mechanisms

The Standard requires the use of automatic rejection devices to be incorporated with metal detection and X-ray equipment. The objective is to ensure that rejected products are effectively removed and not accidently reintroduced into the process flow.

The use of belt stop and alarm systems is considered by some to present a greater risk of 'rejected' product being reintroduced into the process flow than automatic rejection systems where the product is positively rejected into a locked container. The Standard permits the use of either rejection mechanism providing there are sufficient controls in place to prevent implicated product being inadvertently placed back into the product flow.

For belt-stop-style metal detector rejection systems, this will typically include the use of a container into which rejected product is placed, which is secured so that only authorised staff can remove the product (similar to the locked-box system used for automatic rejection systems).

CLAUSE REQUIREMENTS

Further guidance

Where the product is packed into metal packaging, an effective alternative test method must be developed – for example, the use of X-ray detectors, metal detection, magnets or product inspection prior to packing.

The following additional controls should be considered to ensure that rejected product is effectively segregated and managed:

- The removal of affected product should be restricted to trained, authorised staff. This may be supported by restricting access to the product once the belt has stopped (e.g. by using a locked production-line cover and authorised key holders).
- Rejected product may be marked, destroyed or have its label removed to reduce the risk of reintroduction to the process flow.
- The line restart should be restricted to designated personnel who must verify the location of the 'rejected' product prior to restart (i.e. the control panel/button for restart is secure, locked or security-coded).
- A record should be made of each occasion when the belt stops in response to the detection of metal in a product.

4.10.3.3

The site shall establish and implement procedures for the operation and testing of the metal detection or X-ray equipment. This shall include, at a minimum:

- responsibilities for the testing of equipment
- the operating effectiveness and sensitivity of the equipment and any variation to this for particular products
- the methods and frequency of checking the detector
- recording of the results of checks.

Interpretation

Documented metal detector and X-ray procedures

The site must have documented procedures for the operation (including effectiveness and sensitivity) and routine monitoring of metal detector and X-ray equipment. The procedures will identify the individuals responsible for completing the tests.

The frequency of testing must be based on the quantity and type(s) of product. However, the following should be considered:

- start-up and finish of shifts
- product changeovers
- change in machine settings following downtime for repairs
- customer requirements
- regular checks throughout production (these should consider the site's ability to recover and retest product in the event of a failure; therefore a minimum of hourly testing is typically expected).

The testing procedures must be based on the requirements of clause 4.10.3.4 but must also ensure that all relevant parts of the metal detector are operating correctly (e.g. the timing of the rejection system, the memory reset function and any failsafe alarms).

The results of the tests conducted must be documented to demonstrate that all requirements of the monitoring procedure were executed and were within the correct working parameters.

The Standard does not require routine calibration of metal detectors beyond the verification/checking activities described in this section. However, planned maintenance or servicing may have value depending on the machine, the manufacturer's specification, the contract and/or the operating environment.

4.10.3.4

Metal detector testing procedures shall, at a minimum, include:

- use of test pieces incorporating a sphere of metal of a known diameter selected on the basis of risk.

 The test pieces shall be marked with the size and type of test material contained
- tests carried out using separate test pieces containing ferrous metal, stainless steel and typically non-ferrous metal, unless the product is within a foil container where a ferrous-only test may be applicable
- a test to prove that both the detection and rejection mechanisms are working effectively under normal working conditions

CLAUSE **REQUIREMENTS** tests of the metal detector by passing successive test packs through the unit at typical line operating • checks of failsafe systems fitted to the detection and rejection systems. In addition, where metal detectors are incorporated on conveyors, the test piece shall be passed as close as possible to the centre of the metal detector aperture. Wherever possible, the test piece shall be inserted within a clearly identified sample pack of the food being produced at the time of the test. Where in-line metal detectors are used, the test piece shall be placed in the product flow wherever this is possible and the correct timing of the rejection system to remove identified contamination shall be validated. Testing of in-line metal detectors shall be completed during both line start-up and at the end of the production period. Interpretation Metal detector checking procedures The company must establish procedures for the operation and routine monitoring of the metal detector. Industry best practice, manufacturers' quidelines and specific customer requirements (clause 4.10.1.3) should be considered when developing these procedures. Failsafe systems are systems that monitor their own functions and raise an alarm (usually audible) if something stops working. For example, if a product rejection system is powered by compressed air and the air supply fails, this will sound the alarm immediately allowing staff to investigate the fault, rather than waiting until the next metal detector check finds a problem. Where these systems exist, it is important to run occasional checks to ensure that the failsafe system itself is operating (e.g. that the alarm will sound).

4.10.4 MAGNETS

AI		

4.10.4.1

REQUIREMENTS

on their current equipment.

The type, location and strength of magnets shall be fully documented. Procedures shall be in place for the inspection, cleaning, strength testing and integrity checks. Records of all checks shall be maintained.

The Standard does not expect sites to purchase new metal detection equipment if there is no failsafe system.

Interpretation

Magnets

Some sectors of the food industry (e.g. grinding of cereals, coffee etc.) employ magnets to reduce or remove metal fragments. Where these are used, it is important to document the type (e.g. electromagnet or permanent magnet), location and strength of the magnet.

Magnets are not an alternative to metal detectors but an additional control mechanism, and factories using magnets must still comply with the requirements of section 4.10.3.

The magnet's strength should be designed to ensure that it is sufficient to capture metal foreign bodies. A number of factors should be considered when determining the correct strength; for example, the type of product (e.g. the size of the food particles), the width of the conveyor belt, chute or other equipment in which the magnets are located, and the flow rate of the food or raw material.

Documented procedures must be in place to ensure:

- routine inspection (e.g. visual inspection for damage and the presence of captured metal fragments)
- cleaning the ability of a magnet to capture a foreign body can be hampered if dirt or other material is allowed to collect on the magnet's surface
- strength testing (e.g. by using a magnetic meter (measuring the magnet's strength in tesla) or through the use of a third-party calibration service).

Records of all checks, recalibrations or servicing must be maintained.

Good practice for monitoring a magnet's performance includes locating a second 'policing' magnet as close to the first as possible. Any metal found on this second magnet indicates that the 'process' magnet is not performing satisfactorily and is failing to remove all metal particles.

4.10.5 OPTICAL SORTING EQUIPMENT

CLAUSE	REQUIREMENTS
4.10.5.1	Each unit shall be checked in accordance with the manufacturer's instructions or recommendations. Checks shall be documented.
Interpretation	Optical sorting equipment Optical sorting devices are commonly used in some industries to remove unsatisfactory products or contaminants, usually on the basis of colour or variance from a reference material. Where equipment is in use, procedures need to be developed for the maintenance and testing of the equipment. This is usually developed with the manufacturer when the equipment is installed and commissioned.
	Records of all checks and servicing must be maintained.

4.10.6 CONTAINER CLEANLINESS – GLASS JARS, CANS AND OTHER RIGID CONTAINERS

CLAUSE	REQUIREMENTS
4.10.6.1	Based on risk assessment, procedures shall be implemented to minimise foreign-body contamination originating from the packaging container (e.g. jars, cans and other pre-formed rigid containers). This may include the use of covered conveyors, container inversion and foreign-body removal through rinsing with water or air jets.
Interpretation	Procedures Where packaging containers are supplied to the production site in a rigid format (e.g. empty cans, bottles or glass jars), there is an increased risk of contamination of the container during storage and transit before filling. Glass containers carry the additional risk of damage during transit.
	The site needs to consider the potential risks associated with the containers and introduce appropriate controls to reduce the risk. For example, it is usual for such containers to be inverted and cleaned prior to use and for glass jars and bottles to be subject to automatic or manual (by exception) inspection before use.
	Documented procedures, based on risk assessment, must be available to address the potential risks.
4.10.6.2	The effectiveness of the container-cleaning equipment shall be checked and recorded during each production. Where the system incorporates a rejection system for dirty or damaged containers, the check shall incorporate a test of both the detection and effective rejection of the test container.
Interpretation	Effectiveness of container cleaning In-line cleaning and automatic rejection systems are not a requirement of the Standard, but the use of such systems is strongly encouraged. Where these systems are present, they must be checked and records maintained of checks.
	Consideration must also be given to the action required in the event of a breakage after cleaning (clause 4.9.3.3).

4.11 HOUSEKEEPING AND HYGIENE

FUNDAMENTAL

Housekeeping and cleaning systems shall be in place which ensure appropriate standards of hygiene are maintained at all times and the risk of product contamination is minimised.

Interpretation

Housekeeping is general tidiness and hygiene is standard of cleanliness, sometimes also referred to as sanitation.

The site must be maintained to a suitable level of cleanliness. Control of hygiene must be achieved through schedules of cleaning and policies on housekeeping based on risk assessment. This must be demonstrated through documented and monitored systems. The methods of cleaning themselves must not pose a risk of product contamination (e.g. from cleaning areas adjacent to open product).

CLAUSE	REQUIREMENTS		
4.11.1	The premises and equipment shall be maintained in a clean and hygienic condition.		
Interpretation	Cleanliness of premises and equipment It is important that the site, manufacturing environment and equipment are routinely cleaned to an appropriate standard of cleanliness to prevent potential contamination (e.g. with allergens or micro-organisms) and to prevent quality issues such as taint from previously manufactured products.		
The Standard requires (clause 4.11.3) that appropriate limits of acceptable cleaning performance be defined.			
	During the course of the audit, equipment that is not currently operating will be opened and inspected to assess whether cleaning has been completed appropriately and in accordance with the site's policies (including the acceptable limits), as well as to assess post-cleaning checks (clause 4.11.5). Production lines that are running will not be stopped for inspection.		
4.11.2	Documented cleaning procedures shall be in place and maintained for the building, plant and all equipment. Cleaning procedures for the processing equipment and food contact surfaces shall, at a minimum, include:		
	 responsibility for cleaning item/area to be cleaned frequency of cleaning method of cleaning, including dismantling equipment for cleaning purposes where required cleaning chemicals and concentrations cleaning materials to be used cleaning records and responsibility for verification. 		
	The frequency and methods of cleaning shall be based on risk.		
	The procedures shall be implemented to ensure appropriate standards of cleaning are achieved.		

CLAUSE

REQUIREMENTS

Interpretation

Documented cleaning procedures

Documented cleaning procedures must be in place to ensure consistent and effective cleaning and as a guide for training purposes. When documenting such procedures, an emphasis should be placed on the processing equipment and food contact surfaces. The procedures must be in sufficient detail for the cleaning to be carried out to a consistently acceptable standard. In the majority of sites, good practice would normally include six stages of cleaning:

- remove gross debris (e.g. sweep or wipe)
- rinse with water
- wash with detergent solution using hot water
- rinse
- dry
- sanitise.

Where equipment requires different levels of cleaning (e.g. between products, or between daily and weekly cleans), each requirement should be clearly detailed and specific to the item of equipment. These procedures need to be reviewed and updated whenever changes to the equipment and areas to be cleaned occur.

In addition, a good cleaning instruction would include:

- a unique method of reference that can be quoted on paperwork (e.g. cleaning records)
- photographs of equipment, which are useful for identifying equipment and for highlighting areas that are difficult to clean or form key check/verification points
- the appropriate protective clothing or equipment that should be worn when cleaning or handling cleaning chemicals.

Example

SITE AREA: Production WEEK COMMENCING:

			MON		TUE		WED		THU		FRI		SAT		SUN	
METHOD	EQUIPMENT/ AREA	FREQUENCY	Clean Sign	Check Sign

A1	A2 Bowl Mixer 1	Daily														
A1	A2 Bowl Mixer 2	Daily														
A1	A3 Spiral Chiller	Daily														

DOCUMENT REFERENCE	ISSUE DATE/VERSION NUMBER	ISSUE/AUTHORISED BY

Cleaning record

4.11.3

Limits of acceptable and unacceptable cleaning performance shall be defined for food contact surfaces and processing equipment. These limits shall be based on the potential hazards relevant to the product or processing area (e.g. microbiological, allergen, foreign-body contamination or product-to-product contamination). Therefore, acceptable levels of cleaning may be defined by visual appearance, ATP bioluminescence techniques (see glossary), microbiological testing, allergen testing or chemical testing as appropriate.

The site shall define the corrective action to be taken when monitored results are outside of the acceptable limits.

Where cleaning procedures are part of a defined prerequisite plan to control the risk of a specific hazard, the cleaning and disinfection procedures and their frequency shall be validated and records maintained. This shall include the risk from cleaning chemical residues on food contact surfaces.

CLAUSE REQUIREMENTS

Interpretation

Cleaning performance limits

At a minimum, limits of acceptable and unacceptable cleaning performance must be defined for:

- food contact surfaces
- processing equipment.

The limits need to be based on risk, and this should be used for assessing whether the cleaning undertaken is of an acceptable standard. Acceptable limits may be based on visual inspection, ATP monitoring or specific analysis such as microbiological, allergen or chemical testing. For example, where the cleaning is principally designed to provide a clean processing environment, an assessment of 'visually clean' may be sufficient. However, where the level of cleaning is to ensure a sterile food contact surface to make sure that all traces of an allergen have been removed or to prevent cross-contamination of different meat species, the level of acceptable cleaning performance may need to be based on more rigorous checks such as the results of ATP, microbiological or allergen tests.

Where the cleaning procedure forms part of a defined prerequisite (section 2.2) designed to manage a specific hazard (e.g. allergen cross-contamination), then the procedure must be validated to confirm that the specified cleaning method, chemicals and concentrations are capable of consistently achieving the level of performance required. Records of validation must be maintained.

When designing and validating cleaning procedures, cleaning chemical residues must be considered so that they cannot become a source of product contamination (e.g. manufacturer's instruction must be followed regarding rinse methods). Cleaning checks should include hard-to-reach locations as well as surfaces and those locations that are easy to reach, effectively confirming satisfactory cleaning of all surfaces and areas.

Where results are outside of the acceptable limits, the site's procedures should ensure that corrective action is taken (e.g. by repeating the cleaning process and rechecking the standard of cleaning). The exact action will depend on the type of cleaning, the check methodology and the acceptable levels that have been defined.

4.11.4

The resources for undertaking cleaning shall be available. Where it is necessary to dismantle equipment for cleaning purposes or to enter large equipment for cleaning, this shall be appropriately scheduled and, where necessary, planned for non-production periods. Cleaning staff shall be adequately trained or engineering support provided where access within equipment is required for cleaning.

Interpretation

Training and resources

Appropriate resources are required to ensure that all cleaning is completed correctly and to the appropriate standard. These resources will include:

- cleaning equipment
- cleaning chemicals (e.g. detergents)
- trained personnel. (As per the requirements of clause 7.1, all cleaning must be carried out by trained staff.

 Training records must demonstrate that the relevant training has been completed and must cover all staff involved in cleaning activities, including employment agency and temporary staff.)

Where specialist resources or activity are required (e.g. to dismantle or enter large equipment), this must be appropriately scheduled and, where necessary, planned for non-production periods.

Full support must be provided by engineering, either by additional training or by having engineering staff present during these cleaning operations.

4.11.5

The cleanliness of equipment shall be checked before equipment is released back into production. The results of checks on cleaning, including visual, analytical and microbiological checks, shall be recorded and used to identify trends in cleaning performance and to instigate improvements where required.

Interpretation

Cleaning inspection and sign-off

An authorised member of staff (e.g. line supervisor, quality assurance supervisor or production manager) must formally accept equipment back into operation following an inspection, to confirm that the cleaning has been completed satisfactorily.

The results of checks on cleaning, including visual or analytical checks, must be recorded. These records must be used to identify trends in cleaning performance and to instigate improvements where required. For example, trends and potential changes could be discussed during management meetings (clause 1.1.4).

Where changes in cleaning regimes are required (e.g. to prevent the build-up of micro-organisms, biofilm or scale), companies may need access to relevant expertise or advice.

CLAUSE REQUIREMENTS Cleaning equipment shall be: hygienically designed and fit for purpose suitably identified for intended use (e.g. colour-coded or labelled) cleaned and stored in a hygienic manner to prevent contamination.

Interpretation

Cleaning equipment

Cleaning equipment, including any equipment or utensils used for cleaning activities, must be suitable for the purpose for which it is intended and capable of achieving the desired level of cleaning. For example, equipment would not be suitable if it:

- had the potential to shed fibres
- was not hygienically designed (to facilitate easy cleaning after use).

Equipment must be clearly identified at all times (by colour-coding and/or labelling). This is necessary to ensure that different types of equipment are clearly distinguishable (e.g. floor-cleaning equipment must be distinguishable from items designated for cleaning production equipment). They must also be stored hygienically and in a manner that prevents contamination (e.g. not stored in contact with the floor).

The operation of tray/rack washes to ensure that they operate effectively should also be considered; for example, checks could include the visual inspection of cleaned trays, monitoring water temperature or the chemical concentration of detergent, or microbiological swabbing.

Further guidance

Developing an effective cleaning procedure

In order for cleaning to be effective, it is important that the procedures are designed for the specific item, area or site. A generic, off-the-shelf procedure probably wouldn't guarantee a sufficient standard of cleaning. For example, an identical work surface in an area handling bakery products would need to be treated differently from one in a meat-handling area. This would need to be assessed during the development and risk assessment stage. The complexity of the process and equipment, the types of product manufactured, the ease with which debris can be removed, and the need to manage specific hazards (e.g. specific micro-organisms or allergens) are also factors to consider.

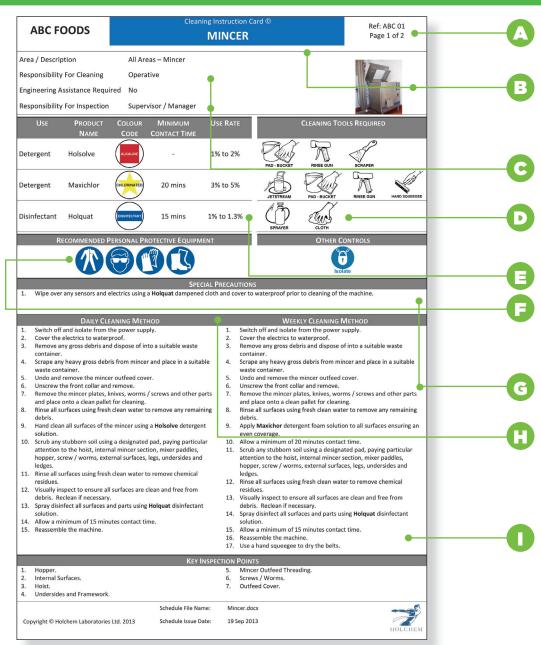

Developing a cleaning procedure can be done in a few simple steps:

- Step 1: Set the required standard of cleaning (clause 4.11.3)
 Consider legislation, customer requirements, industry or category best practice, etc. The risk
 assessment should consider the prevention of contamination from previous products, as well as address
 potential microbiological, chemical or allergen concerns.
- Step 2: Develop draft procedures (clause 4.11.2)
 Ensure all items, areas and equipment are defined and included within the procedures. Think about the order of cleaning too so that cleaned equipment is not re-contaminated by subsequent cleaning activity.
- Step 3: Validate the draft procedures (clause 4.11.3)
 Validation is used to confirm that the required standard of cleaning (Step 1) is met. The Standard requires that cleaning procedures which form part of a defined prerequisite (i.e. procedures that are used to control a specific hazard such as allergen cross-contamination) must be validated to ensure they are effective and deliver the intended level of cleaning. However, it is also good practice for all cleaning procedures to be validated.
- Step 4: Finalise procedures and associated documentation (e.g. cleaning records and sign-off)
 Records must be kept that show what type of cleaning was completed, when it was completed, who did the cleaning and who checked and signed off the cleaning as acceptable (a requirement of clause 4.11.2).
- Step 5: Train relevant staff (clause 4.11.4)
- Step 6: Complete ongoing monitoring and verification (clauses 4.11.2 and 4.11.5).

CLAUSE

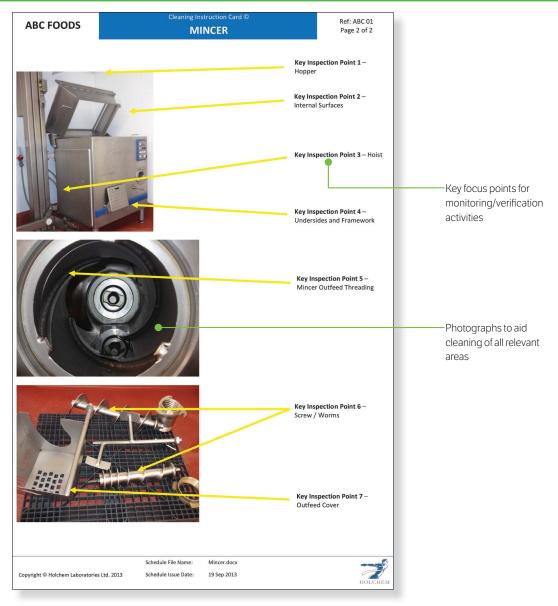

REQUIREMENTS

Example

- A Unique method reference
- Clear identification of area or equipment
- Responsibility for cleaning & sign off
- Cleaning utensils/tools to be used
- © Cleaning chemicals with appropriate concentrations and instructions
- Appropriate protective clothing
- Instructions for dismantling & other precautions
- Cleaning frequency (this may contain more than one section if the equipment has routine and periodic deep cleaning)
- Stepwise cleaning instructions

Example of cleaning procedures (continues on next page)

(Example of a cleaning procedure provided courtesy of Holchem Laboratories Ltd)

Example of cleaning procedures (continued)

Further guidance

Ongoing checks

Verification is the application of checks or tests, at regular intervals, to ensure the cleaning procedure is still working and continues to deliver the required level of cleaning. Verification of cleaning may include internal audits, record reviews, swabs or tests of the cleaned equipment and the assessment of staff to ensure they have a clear understanding of the cleaning procedure.

Cleaning procedures should be reviewed whenever there are changes to the area, equipment or processes including the introduction of new products or the use of new ingredients.

Quick tips

- Ensure all equipment and areas are included.
- Discuss cleaning needs with equipment and chemical suppliers.
- Remember that validation and verification are needed for cleaning activities.

4.11.7 CLEANING IN PLACE (CIP)

Interpretation

CIP is a method of cleaning the interior surfaces of pipes, vessels, process equipment, filters and associated fittings without disassembly. CIP equipment is specialist and therefore operator training is important.

CLAUSE	REQUIREMENTS						
4.11.7.1	All CIP equipment shall be designed and constructed to ensure effective operation. This shall include:						
	 validation confirming the correct design and operation of the system an up-to-date schematic diagram of the layout of the CIP system where rinse solutions are recovered and reused, an assessment of the risk of cross-contamination (e.g. due to the re-introduction of allergen). 						
	Alterations or additions to the CIP system shall be authorised by a suitably competent individual before changes are made. A record of changes shall be maintained.						
	The system shall be revalidated at a frequency based on risk, and following any alteration or addition.						
Interpretation	Effective operation, maintenance and validation of CIP systems Effective CIP starts with the design and set-up of the system. The site will therefore need validation to confirm that the design, set-up and proposed operation of the system are suitable for the intended use. For example:						
	 knowledge of the layout of the pipework and the position of valves, spray balls and holding tanks is essential to ensure that the system will operate consistently and effectively and that there are no dead spots or areas where cross-contamination between cleaning chemicals and product can occur correct design of the CIP system to ensure good coverage of cleaning solutions with suitable drainage to avoid pools of solutions assurance that the intended cleaning will be effective (e.g. that the food/products intended to be used on the equipment will be effectively removed during cleaning) consideration of the risk of potential contaminants (e.g. allergens) from previous products being re-introduced onto the equipment during the collection, recycling or re-use of solutions (e.g. rinse solutions). 						
	Confirmation of the correct design and set-up may be achieved by an inspection report (e.g. from the equipment manufacturer) or by separate documented validation.						
	A schematic plan or diagram should be provided by the supplier when the system is installed and must be updated whenever a change is made, including to software, equipment and operation of the system.						
	Issues are most likely to occur where CIP systems are modified or extended. Therefore, controls must be in place to ensure that all changes (e.g. engineering modifications, changes to the programming or operation of the system, and changes to consumables such as the detergents used) are made only by a suitably trained and competent individual. This could be achieved by, for example:						
	 having a company policy that permits modifications only by the manufacturer of the equipment training engineering staff password-protecting the system with different levels of access to prevent unauthorised modifications to programme parameters or software. 						
	Records of changes must be maintained.						
	The site should use risk assessment to determine suitable intervals for revalidation of the CIP system to ensure its continuing effectiveness. The CIP system will also require revalidation following any alterations or additions to ensure it continues to operate as expected.						
4.11.7.2	Limits of acceptable and unacceptable performance for key process parameters shall be defined to ensure the removal of target hazards (e.g. soil, allergens, micro-organisms, spores). At a minimum these parameters shall include:						
	 times for each stage detergent concentrations flow rate and pressure temperatures. 						
	These shall be validated and records of the validation maintained.						

CLAUSE	REQUIREMENTS
Interpretation	Operation of CIP equipment The CIP process parameters and tolerances must be identified and limits of acceptable and unacceptable performance set. The actual values of acceptable and unacceptable performance will depend on the target hazards that the CIP cleaning is intended to remove and this in turn will depend on the product types being processed. Specific hazards may include, for example, soil, allergens and/or vegetative micro-organisms. The Standard identifies minimum key parameters that need to be defined, and their limits must be validated
	to confirm effective removal of the identified hazards.
4.11.7.3	The CIP equipment shall be maintained by suitably trained staff to ensure effective cleaning is carried out. This shall include:
	 detergent concentrations shall be checked routinely recovered post-rinse solutions shall be monitored for build-up of carry-over from the detergent tanks filters, where fitted, shall be cleaned and inspected at a defined frequency where used, flexible hoses shall be stored hygienically when not in use, and inspected at a defined frequency to ensure that they are in good condition.
Interpretation	Maintenance of the CIP system A planned maintenance programme must be in place to ensure all aspects of the CIP system are in good working order. At a minimum, this should include:
	 monitoring detergent concentrations and post-rinse solutions inspection, cleaning and storage of filters and flexible hoses where they are part of the CIP system.
	The frequency of maintaining the different aspects of the programme should be based on risk. For example, good practice normally includes ensuring detergent tanks are drained, cleaned and filled, with a log of these activities to confirm that they have been completed to schedule.
	Monitoring and inspection may be undertaken by trained site staff (e.g. engineers) or carried out as part of a service agreement with the supplier or with the service company maintaining the system. A report of the inspection (that includes an overview of the scope of the inspection, any recommendations for improvement, and confirmation or otherwise of the effectiveness of the system) should be kept.
4.11.7.4	CIP facilities, where used, shall be monitored at a defined frequency based on risk. This may include:
	 monitoring of process parameters defined in clause 4.11.7.2 ensuring correct connections, piping and settings are in place confirming the process is operating correctly (e.g. valves opening/closing sequentially) ensuring effective completion of the cleaning cycle monitoring for effective results, including draining where required.
	Procedures shall define the action to be taken if monitoring indicates that processing is outside the defined limits.
Interpretation	Monitoring of CIP To ensure the ongoing effectiveness of the CIP system, it is important to routinely monitor the operation of the system. This will include checks of connections, piping and settings prior to starting the cleaning process and a post-cleaning confirmation of effective cleaning.
	The frequency of monitoring should be based on risk.

4.11.8 ENVIRONMENTAL MONITORING

Risk-based environmental monitoring programmes shall be in place for pathogens or spoilage organisms. At a minimum, these shall include all production areas with open and ready-to-eat products.

Interpretation

The aim of the environmental monitoring programme is to identify any potential risks in the production and open-product areas so that they can be appropriately managed and prevented from becoming the source of product contamination (which could lead to non-conforming product, a customer complaint or other incidents).

An effective programme can, for example, be used to:

- confirm the effectiveness of cleaning and hygiene activities and identify any areas that require further activity
- prevent product contamination by acting as an 'early warning' identifying potential contamination from the site facilities before they affect products.

The design and structure of this programme will depend on the nature of the products being handled and the potential hazards associated with them. Sites are not expected to 'opt out' of this requirement by determining that they have a low-risk product or environment; completion of a risk assessment (clause 4.11.8.1) will identify relevant hazards, suitable monitoring techniques and appropriate monitoring frequencies.

CLAUSE	REQUIREMENTS
4.11.8.1	The design of the environmental monitoring programme shall be based on risk, and at a minimum include: • sampling protocol • identification of sample locations • frequency of tests • target organism(s) (e.g. pathogens, spoilage organisms and/or indicator organisms) • test methods (e.g. settle plates, rapid testing and swabs) • recording and evaluation of results. The programme and its associated procedures shall be documented.

Interpretation

Risk-based environmental monitoring programme

The programme must be based on risk assessment. At a minimum this will include:

- a sampling protocol. It is important to ensure that the sampling method does not inadvertently create
 false positives (e.g. by allowing post-sampling contamination or growth of organisms) or false negatives
 (e.g. by killing organisms in the sample before the test is completed). Sampling must be appropriate for
 the target organisms, test methods and locations sampled; techniques may include swabs, air sampling,
 water/liquid samples etc.
- identification of suitable test locations, taking into account:
 - significance of the area or equipment in terms of the potential to affect food safety; for example, food contact surfaces, non-food contact areas which are in close proximity to open products, and nonfood contact areas some distance away from open products (e.g. floors, walls and drains)
 - areas or parts of equipment that are difficult to clean and could harbour pathogens
 - areas of the site or equipment which previously tested positive
 - $-\$ areas where scientific literature has identified a specific risk (e.g. drains)
- frequency of tests, taking into account:
 - products that support the growth of pathogens. These require a greater frequency of testing than those that do not support growth
 - locations with previous positive results or an upward trend towards an action level (clause 4.11.8.2).
 These are likely to require increased testing to confirm the effectiveness of the action taken
- target organisms. These may include specific pathogens that present a risk to the product or environment (e.g. *Listeria* spp in wet environments or Enterobacteriacae in dry environments), specific spoilage organisms (e.g. yeast or mould) or indicator organisms (e.g. total plate count, total coliforms)
- test methods. Rapid on-site and laboratory tests are available, and sites should consider the requirements of section 5.6 when deciding which methods and/or laboratories to use
- evaluation of results. The significance of the results and any actions required must be considered (clause 4.11.8.2).

CLAUSE REQUIREMENTS The programme should also review any legal requirements in the country or region (e.g. relating to types of products, organisms of concern, or frequency or minimum number of tests). The auditor will expect to see the risk assessment and the subsequent plan along with testing protocols, procedures and evidence that the site is completing the plan to schedule. Appropriate control limits shall be defined for the environmental monitoring programme. 4.11.8.2 The company shall document the corrective action to be taken when monitored results indicate a failure to meet a control limit, or when monitored results indicate an upward trend of positive results. Interpretation **Control limits** The site will need to establish appropriate control limits and the actions to be taken if these are exceeded or when there is a trend towards increasingly positive results. The control limits and actions may be based on: • the organism measured, its level and the location of the positive result • when the testing was completed (e.g. was the sample taken pre- or post-cleaning?) • any legal or customer limits. The site may find it useful to use root cause analysis to establish preventive action (e.g. in the case of recurrence of pathogens at a set location). 4.11.8.3 The company shall review the environmental monitoring programme at least annually and whenever there are: • changes in processing conditions, process flow or equipment new developments in scientific information • failures of the programme to identify a significant issue (e.g. regulatory authority tests identifying positive results which the site programme did not) • product failures (products with positive tests) consistently negative results (e.g. a site with a long history of negative results should review its programme to consider whether the correct parts of the factory are being tested, whether the testing is being conducted correctly, whether the tests are for the appropriate organisms, etc.). Interpretation Review of the environmental monitoring programme The review of the programme could be accomplished as part of the HACCP review or as a separate review process. The Standard lists several points which might prompt a review, including: changes in processing as these could, for example, affect the ease of cleaning or susceptibility of products to contamination • publication of new scientific information, such as the identification of a micro-organism not previously associated with a specific product type, or information relating to the survival of a pathogen in specific environmental conditions when independent testing (e.g. by a regulatory authority) identifies positives not previously identified by the site's own tests • when a positive test on a product implicates the effectiveness of the environmental monitoring

• an extensive lack of positive results; such results should call into question whether the correct locations are being tested in the correct way for the correct organisms. The aim of the programme is, after all, to

identify areas of concern.

4.12 WASTE/WASTE DISPOSAL

Waste disposal shall be managed in accordance with legal requirements and to prevent accumulation, risk of contamination and the attraction of pests.

Interpretation

Waste disposal systems (for example, in production and storage areas, as well as in waste collection areas or rooms) must ensure that the risk of contamination to products is minimised through the control of cross-contamination and control of pests. Disposal must comply with legal requirements.

Good practice should ensure that containers used for either raw material storage or handling, or for finished product storage, are not used for collecting waste. Instead, waste must be collected in appropriate, designated waste containers.

CLAUSE	REQUIREMENTS
4.12.1	Where licensing is required by law for the removal of waste, it shall be removed by licensed contractors and records of removal shall be maintained and available for audit.
Interpretation	Licensing and legislation Waste contractors must be appropriately licensed and/or approved where this is required by local law. Where legislation exists for specific waste streams (e.g. disposal of meat products), this must be complied
	with; such legislation may include requirements for segregation or specific methods of disposal.
	Records of removal must be maintained and available for audit.
4.12.2	Internal and external waste collection containers and rooms housing waste facilities shall be managed to minimise risk. These shall be:
	clearly identified
	designed for ease of use and effective cleaning
	well maintained to allow cleaning and, where required, disinfection
	emptied at appropriate frequencies. Systemal wests containers shall be appropriate.
	External waste containers shall be covered or doors kept closed as appropriate.
Interpretation	Waste storage Waste collection containers and rooms housing waste facilities must be managed to minimise the risk of contamination of products. Particular consideration must be given to:
	 identification of waste containers and storage areas to ensure waste is collected only in designated containers/areas ease of cleaning keeping facilities well maintained emptying at appropriate frequencies
	 keeping external waste containers covered or room doors closed, thus ensuring that waste cannot fall out of containers or stray out of designated rooms to cause a contamination risk the pest control implications of external waste collection areas.
4.12.3	If unsafe products or substandard trademarked materials are transferred to a third party for destruction or disposal, that third party shall be a specialist in secure product or waste disposal and shall provide records which include the quantity of waste collected for destruction or disposal.
Interpretation	Unsafe and trademarked waste Requirements for the disposal of trademarked waste must be defined within a contract with the waste disposal contractor. Records of destruction or disposal must be maintained. The objective is to ensure that waste products do not re-enter the food supply chain once sent for disposal. If unsafe products are transferred to a third party for destruction, the third party must be a specialist in secure product or waste disposal and must provide records which include the quantity of waste collected.

4.13 MANAGEMENT OF SURPLUS FOOD AND PRODUCTS FOR ANIMAL FEED

Effective processes shall be in place to ensure the safety and legality of by-products of the primary processing activity of the site.

Interpretation

The site's procedures to control the handling and storage of surplus food and by-products must ensure that safety and legality are maintained.

CLAUSE	REQUIREMENTS
4.13.1	Surplus customer-branded products shall be disposed of in accordance with customer-specific requirements. Customer brand names shall be removed from packed surplus products under the control of the factory before the product enters the supply chain, unless otherwise authorised by the customer.
Interpretation	Surplus customer-branded products This clause covers the situation where a surplus product is not required by the intended customer (e.g. because of a fall in predicted orders), but is still suitable for sale to alternative customers. It does not include sales to staff or donations to charity, which are covered separately in clause 4.13.2.
	The release of surplus product to alternative customers must only take place in accordance with the original brand owner's specific requirements. For example, in many cases the product packaging (or associated documentation) will refer to the brand owner and these brand names will need to be removed before the product leaves the site.
4.13.2	Where customer-branded products which do not meet specifications are sold to staff or passed on to charities or other organisations, this shall be with the prior consent of the brand owner. Processes shall be in place to ensure that all products are fit for consumption and meet legal requirements.
Interpretation	Staff shops and donations of products to charity Many companies sell products to staff or donate them to charity when they are not required by the intended customer (e.g. because of a fall in predicted orders, minor cosmetic damage to packaging, or failure to meet the brand owner's specification).
	In many cases the product packaging (or associated documentation) will refer to the brand owner and therefore release to charity or staff must only take place with the prior consent of the brand owner. It is not necessary for the site to obtain this consent for each individual batch of product or on each occasion that the product is sent to a charity; however, the brand owner's policy or permission must be defined (e.g. in a policy document or within the company's contract).
	All products (customer-branded and own brand) must still be safe, legal (e.g. meet legal requirements for labelling) and fit for consumption; therefore the site should have documented procedures which detail the product assessment and release process. Staff responsibilities, including which staff have authorisation to release products for staff sale or charitable donation, should also be made clear.
4.13.3	By-products and downgraded/surplus products intended for animal feed shall be segregated from waste and protected from contamination during storage. Products for animal feed shall be managed in accordance with the relevant legislative requirements.
Interpretation	Food for animal feed In many parts of the world, there are specific regulations relating to the suitability of products and by-products for inclusion in animal feed (e.g. EU legislation on animal by-products and the control of transmissible spongiform encephalopathies). It is essential that, where products and by-products are supplied for animal feed, the site is aware of, and complies with, the relevant legislation. There are several recognised feed schemes and, where applicable, certification to such a scheme may be required. The animal feed contractor must also be appropriately licensed.
	Materials for inclusion in animal feed must be segregated from other waste streams and managed to prevent contamination.

4.14 PEST MANAGEMENT

The whole site shall have an effective preventive pest management programme in place to minimise the risk of infestation and resources shall be available to respond rapidly to any issues which occur to prevent risk to products.

Pest management programmes shall comply with all applicable legislation.

Interpretation

Management of pests must be undertaken at a level commensurate with the needs of the whole site, including temporary or seasonal facilities and all storage units, based on the:

- nature of identified potential pests, including rodents, insects and birds
- characteristics of raw materials (regarding their potential for stored insect pests)
- equipment
- finished products
- process
- site and environment (e.g. prevention of ingress and the removal potential pest harbourage)
- potential for future pest risks
- legal requirements in the country or region where the site is located.

Where instances of pest ingress (i.e. single occasion or low numbers) occur, these need to be appropriately investigated and actioned but must not be deemed as loss of control. However, where there is pest infestation (i.e. evidence of large numbers of pests breeding within the building or site over a period of time), this must be regarded as loss of control and a lack of maintenance of the pest management programme, and will lead to a major non-conformity being awarded.

BRC Global Standards publishes a separate best-practice guideline on pest management, which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

CLAUSE	REQUIREMENTS
4.14.1	If pest activity is identified, it shall not present a risk of contamination to products, raw materials or packaging.
	The presence of any infestation on site shall be documented in pest management records and be part of an effective pest control programme to eliminate or manage the infestation so that it does not present a risk to products, raw materials or packaging.
Interpretation	Pests present on site Where pest activity is identified, for example during site inspections (clauses 4.14.2 and 4.14.10) or reported by staff (clause 4.14.12), actions must be taken to ensure the risk of contamination of products, raw materials or packaging is avoided. The site will therefore need to record and assess any reported pest activity in a timely manner to ensure appropriate action can be taken. This may include action by the site (e.g. isolation of at-risk product) or by its approved pest management contractor (clause 4.14.2).
	Where an infestation occurs, this must be clearly documented and effectively managed (clause 4.14.8).
4.14.2	The site shall either contract the services of a competent pest management organisation or have appropriately trained staff for the regular inspection and treatment of the site to deter and eradicate infestation.
	The frequency of inspections shall be determined by risk assessment and shall be documented. The risk assessment shall be reviewed whenever:
	 there are changes to the buildings or production processes which could have an impact on the pest management programme there has been a significant pest issue.
	Where the services of a pest management contractor are employed, the service scope shall be clearly defined and reflect the activities of the site.
	Service provision regardless of the source shall meet with all applicable regulatory requirements.

CLAUSE

REQUIREMENTS

Interpretation

Pest management system

There must be regular inspection and, where appropriate, treatment of the site to deter and eradicate infestation. The frequency of inspection and treatment of the premises must be based on the product risk, including the age, design and location of the buildings and equipment.

Pest management is often contracted to external companies, which may need to be licensed or approved by local or national authorities. The contractor must demonstrate competence (evidence could, for example, include membership of a national trade association, training records, licence or CEPA certification to EN16636 for pest management services).

All pest management activity must be in accordance with legislative requirements. For example, in some countries you must have a licence to purchase and use certain chemicals (e.g. rodenticides in the EU).

The scope of the service must be clearly defined (e.g. in a contract) and should include provision for additional treatments where required to eradicate any infestation that may occur.

Where pest management is handled in-house, responsible employees must have appropriate training, as evidenced by training records (clause 4.14.3).

A review of the system should be made when changes to the site or processes occur, but where no changes have been made, an annual review is also good practice. The auditor will expect to see that the frequency of inspections is appropriate to the nature of the site, and takes into account any infestation or issues with pests which have been highlighted by monitoring activity.

Where automated monitoring or inspection is in place, it can affect the frequency of inspections (e.g. online monitoring devices can report to the site and contractor, allowing the contractor to advise whether a callout or other action is required). It is not a replacement for visits but can lead to more focused visits that are not just bait-point checking.

4.14.3

Where a site undertakes its own pest management, it shall be able to effectively demonstrate that:

- pest management operations are undertaken by trained and competent staff with sufficient knowledge
 to select appropriate pest control chemicals and proofing methods and understand the limitations of
 use, relevant to the biology of the pests associated with the site
- staff undertaking pest management activities meet any legal requirements for training or registration
- sufficient resources are available to respond to any infestation issues
- there is ready access to specialist technical knowledge when required
- legislation governing the use of pest control products is understood and complied with
- dedicated locked facilities are used for the storage of pesticides.

Interpretation

In-house pest management

With regard to the need for pest management to be undertaken by trained staff, the auditor will check the appropriate training records for proof of adequate training.

Access to specialist technical knowledge can be obtained by engaging the services of an external contractor or via trade association membership.

In some geographic regions legislation governing the use of pest control products is updated frequently and the appointed staff will need to keep abreast of any changes.

4.14.4

Pest management documentation and records shall be maintained. At a minimum, this shall include:

- an up-to-date plan of the full site, identifying pest control devices and their locations
- identification of the baits and/or monitoring devices on site
- clearly defined responsibilities for the site management and the contractor
- details of pest control products used, including instructions for their effective use and action to be taken in case of emergencies
- any observed pest activity
- details of pest control treatments undertaken.

Records may be on paper (hard copy) or controlled on an electronic system (e.g. an online reporting system).

CLAUSE **REQUIREMENTS** Interpretation Pest management documentation and records Written procedures and inspection documentation must be maintained. These must include: an up-to-date site plan identifying the locations of pest monitoring and control devices. This plan should be reviewed periodically, for instance annually or when there are site changes • identification (e.g. a numbered list) of the types of bait and monitoring devices on site clearly defined responsibilities for site management and the contractor. This should include methods of communication, contact details for the nominated site and contractor personnel, and dates for when review meetings will take place details of the pest control products used and instructions for their safe and effective use records of any pest activity observed • details of pest control activities undertaken. All pest management inspections must be recorded, even when there are only negative findings to report. Records can be in any format as long as they are accessible by the site. For example, during an audit the auditor may review paper-based pest management records or, where records are online, ask the site to access the records and demonstrate use of the online system. Bait stations or other rodent monitoring or control devices shall be appropriately located and maintained to 4.14.5 prevent contamination risk to product. Toxic rodent baits shall not be used within production or storage areas where open product is present except when treating an active infestation. Where toxic baits are used, these shall be secured. Any missing bait stations shall be recorded, reviewed and investigated. Interpretation **Bait stations** Bait stations and other rodent monitoring or control devices must be appropriately designed, located and maintained to limit the potential for contamination of products. This can be achieved by: making them tamper-resistant securing them in place or locating them in positions where accidental movement is unlikely using non-spill formulations • inspecting them routinely at a frequency based on risk assessment or local legislation (this is particularly important for areas where live catch, break-back traps or spring-powered traps are permitted because of the potential for secondary pests, if the caught pests are not removed sufficiently quickly). The pest management specialist should advise on the quantity and siting of the monitoring devices; their locations might be risk-based rather than evenly distributed. When an active infestation is being treated, the location of additional monitoring or control devices should be considered. Rodent bait is generally toxic, so must be controlled to avoid contamination of product. Toxic rodent bait must not be used within production or storage areas where open product is present, except when treating an active infestation. Where this occurs the bait must be secured. Any missing bait stations or missing rodent control devices should be recorded and investigated. Additional action may be required depending on the reason for the absent bait station; for example, to ensure that there is no risk to product and that any pest activity has been appropriately managed. Insect-killing devices, pheromone traps and/or other insect monitoring devices shall be appropriately sited 4.14.6 and operational. If there is a danger of insects being expelled from a fly-killing extermination device and contaminating the product, alternative systems and equipment shall be used. Insect-killing devices Interpretation Where insect-killing devices, pheromone traps or other insect monitoring devices are used, they must be correctly sited and operational. If insects could be expelled from an insect-killing device and contaminate the product, alternative systems and equipment must be used (e.g. those based on sticky-board technology) or the devices must be moved to a more appropriate position.

Equipment must be fully operational. For example, bulbs on insect-killing devices must be changed at regular intervals (in accordance with the manufacturer's instructions) to maintain optimal luminosity

instructions. Documentation must provide evidence of this maintenance.

performance, and pheromone traps must be replenished quarterly or in accordance with the manufacturer's

CLAUSE	REQUIREMENTS
4.14.7	The site shall have adequate measures in place to prevent birds from entering buildings or roosting above loading or unloading areas.
Interpretation	Birds The site (or its pest management contractor) should use a risk assessment approach to establish whether there is any potential for the ingress of birds, or for roosting and nesting at loading or unloading areas, and to assess the measures required to mitigate the risk.
	The expectation here is not necessarily to rebuild or reconfigure facilities; instead, the intention is to recognise any potential problems and take steps to remove or mitigate these risks from birds.
4.14.8	In the event of infestation, or evidence of pest activity, immediate action shall be taken to identify at-risk products and to minimise the risk of product contamination. Any potentially affected products should be subject to the non-conforming product procedure.
Interpretation	Infestation and evidence of pest activity In the event of infestation (clause 4.14.1), immediate action must be taken to eliminate the hazard. This will include identifying and quarantining any potentially affected product so that it can be evaluated in accordance with the site's non-conforming product procedures.
	Action may also include steps to protect other products and inspection by the pest management specialist. Any such infestation and corrective actions taken must be recorded.
4.14.9	Records of pest management inspections, pest proofing and hygiene recommendations and actions taken shall be maintained. It shall be the responsibility of the site to ensure that all of the relevant recommendations made by its contractor or in-house expert are carried out in a timely manner.
Interpretation	Records of pest management inspections Records of pest management will include any recommendations made by the pest management specialist (e.g. changes to inspection frequency or pest-proofing).
	It is the responsibility of the company to ensure that all relevant recommendations made by the pest management specialist are carried out within a suitable timescale and verified for effectiveness. Records of these changes must be maintained.
4.14.10	An in-depth, documented pest management survey shall be undertaken at a frequency based on risk, but at least annually, by a pest control expert to review the pest management measures in place. The survey shall:
	 provide an in-depth inspection of the facility for pest activity review the existing pest management measures in place and make any recommendations for change.
	The survey shall be timed to allow access to equipment for inspection where a risk of stored product insect infestation exists.
Interpretation	Pest management survey

In-depth pest management surveys are in addition to the regular inspections (e.g. monthly checks of bait and traps) conducted as part of the pest management programme (clause 4.14.2).

The aim of these surveys is to:

- review existing measures to provide a critical appraisal of the site's pest management activities to ensure they remain appropriate
- allow an in-depth assessment of the site, equipment and facilities for evidence of pest activity.

Where insects in stored product represent a potential hazard, the visits should be scheduled for a time when access to equipment for inspection purposes is available, so that the greatest value can be gained from the survey. Where pest activity is seasonal in nature, the survey may be timed to coincide with the period of greatest risk.

The review will be completed by a pest management expert (e.g. the pest management contractor's field biologist or a senior technician with a qualification in pest management and many years of experience). Ideally, the expert will also have knowledge of the scope and pest management requirements of the Standard and an understanding of the food manufacturing environment. Ultimately, the site should be satisfied that this expert has sufficient knowledge and experience to conduct the analysis and produce meaningful results.

CLAUSE REQUIREMENTS

It is expected that the surveys will be completed at least annually; however, risk assessment may indicate that a different frequency is required (e.g. where pest issues are seasonal in nature then the frequency may need to increase). The auditor will expect to see the risk assessment that the site has used to determine the appropriate frequency. The results of the surveys should be incorporated into the company management review (clause 1.1.4). This clause applies to all sites, not just those carrying out their own pest management.

BRC Global Standards has produced a separate best-practice guideline to pest management which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

4.14.11

Results of pest management inspections shall be assessed and analysed for trends on a regular basis. At a minimum, results of inspections shall be analysed:

- annually or
- in the event of an infestation.

The analysis shall include results from trapping and monitoring devices to identify problem areas. The analysis shall be used as a basis for improving the pest management procedures.

Interpretation

Periodic assessment

There must be a periodic assessment of pest management inspection results and trends. The review will consider:

- pest control measures
- bait takes
- analysis from trapping and monitoring devices
- · identification of any trends
- action taken
- recommendations for changes or improvement.

At a minimum, this periodic assessment must be conducted annually (or sooner in the event of an infestation).

4.14.12

Employees shall understand the signs of pest activity and be aware of the need to report any evidence of pest activity to a designated manager.

Interpretation

Reporting of pest activity

Any member of staff on the site should be trained to recognise pest activity in production or storage areas, and this can form part of the site's induction and refresher training programme. The content might address typical pests, different types of evidence of pest activity, and the food safety implications. Subsequently, any pest activity witnessed by any member of staff needs to be reported to the designated person.

The identification of the designated person and the process by which information should be reported also need to be communicated to the staff. The designated person will need to record the evidence and assess whether additional action is required.

Further guidance

Introduction to field biologist in-depth pest management surveys

In-depth pest management surveys are carried out by an experienced pest management expert, who usually, although not always, operates under the title of field biologist. This short guide is designed to help address any confusion concerning the role and responsibilities of the field biologist and the service they provide.

The role and responsibilities of the pest management field biologist

An in-depth pest management survey allows an experienced person to examine controls and pest activity and recommend improvements to the pest management strategy if needed.

As it is the pest management technician who delivers the practical routine service, it could be argued that having a second tier of inspection adds complexity and costs to the contract. However, this is not the case. The pest management field biologist is on hand to lead the pest management programme, and should guide the efforts of both site personnel and the pest management technician to eliminate problems and maintain pest-free conditions.

In pest management terms, the field biologist is the most important person working on behalf of the pest management contractor in any food site.

REQUIREMENTS

Clearly set out objectives

For the survey to be successful, the field biologist must have clearly defined objectives:

- To determine the current levels of pest activity throughout the site. This should not be a matter of mere
 bait checking but should encompass the whole of the site, especially in less accessible areas such as
 voids and cable runs, where pests are more likely to be established.
- To assess the quality of work being carried out by the regular pest management technician and, where appropriate, to liaise with that same person.
- To review all pest management related documentation.
- To suggest alternative approaches to resolving problems.
- To liaise with senior site or group management.
- To include checks within the manufacturing plant during shutdown periods, particularly when commodities are being handled or processed that are vulnerable to infestation by stored-product insects (e.g. flour silos).

It is good practice not to carry out an in-depth inspection at the same time as a routine inspection.

Qualifications and experience

Most countries will have formal qualifications for those working with pest management, with many countries operating a legally backed licensing system. Anyone working as a field biologist should at least have a recognised basic pest management qualification available in the country concerned, irrespective of whether it is a legal requirement.

Few countries have formal higher-level pest management qualifications. However, a field biologist should be a senior technician with years of practical pest management experience. Other desirable qualifications, knowledge and skills may include:

- possession of a recognised food safety qualification. Field biologists work closely with food, so should be trained to at least the same level as a food-handling employee
- membership of a relevant continuing professional development (CPD) scheme, if such a scheme exists in the country of operation. At the very least they should be able to demonstrate that they keep up to date with technical and regulatory developments in the pest management field
- knowledge of the scope and content of the food industry standards the site is working to. For example, do they understand the requirements of the Standard and whether the site has to meet any customerspecific requirements?
- knowledge and understanding of the food manufacturing processes operating at the site, particularly when commodities vulnerable to infestation by stored-product insects are being handled or processed
- how to use pest monitoring data to effectively target and measure the success of control measures.
 Using monitoring data to generate trend analyses (as opposed to just counts) is key.

Report format and content

Every pest management specialist has their own format for the report. However, it is the content and not the format that is all-important. The report should include:

Areas inspected

The inspection report should include reference to areas inspected, even where no problems have been found. A list of issues requiring attention without any additional detail is unlikely to provide the depth of information the site requires. If an area has been inspected and found clear, then it is important that this is recorded: it is the contractor's evidence that they have inspected that area, and the food manufacturer's evidence that they have no problems there.

Any problems

Problems relating to, for example, sanitation and building fabrication should be highlighted. These observations should have as their objective either the eradication of an existing infestation, or the prevention of one. Where it is not immediately obvious, the reasons why the observation points to a problem should also be stated, and practical and appropriate recommendations should be made to address these matters.

Current system review

Whether the current pest management system is suitable should be reviewed and, if found to be inadequate or inappropriate, recommendations should be made regarding alternative proactive pest management practices and strategies.

CLAUSE	REQUIREMENTS
Quick tips	 Ensure the field biologist is appropriately experienced and qualified. Ensure that a sufficient number of in-depth surveys are scheduled throughout the year. The actual number must be based on risk assessment. Where appropriate, ensure that these surveys are targeted for relevant seasons or activities (e.g. to allow access to stored product silos). Set out clear objectives. Ensure that the content of the report covers all relevant areas. Ensure that reports are reviewed and, where necessary, actions are taken.
Acknowledge- ment	BRC Global Standards gratefully acknowledges Dr John Simmons of Acheta Consulting Ltd in the preparation of this further guidance.

4.15 STORAGE FACILITIES

All facilities used for the storage of raw materials, packaging, in-process products and finished products shall be suitable for purpose.

Interpretation

The site's procedures for storage must be controlled to ensure they do not pose a risk to products. This includes all raw materials and packaging, intermediates and finished products.

CLAUSE	REQUIREMENTS
4.15.1	Procedures to maintain product safety and quality during storage shall be developed on the basis of risk assessment, understood by relevant staff and implemented accordingly. These may include, as appropriate:
	 managing chilled and frozen product transfer between temperature-controlled areas segregation of products where necessary to avoid cross-contamination (physical, microbiological or allergens) or taint uptake storing materials off the floor and away from walls specific handling or stacking requirements to prevent product damage.
Interpretation	Documented storage procedures The company must consider the potential risks to product safety and quality that may develop during storage. In addition to the points listed in the requirement, the company should also maintain the cleanliness of the storage areas (e.g. with appropriate cleaning procedures and identified frequencies, as evidenced by documented records).
4.15.2	Where appropriate, packaging shall be stored away from other raw materials and finished product. Any part-used packaging materials suitable for use shall be effectively protected from contamination and clearly identified to maintain traceability before being returned to an appropriate storage area.
Interpretation	Storage of packaging In order to avoid product contamination risks from packaging (such as glass) or contamination of unused packaging by products, packaging should be stored away from raw materials and finished product. This may be achieved by use of a dedicated packaging store or a dedicated area of a raw material store. Only packaging required for immediate use should be stored in the actual packing area (clause 6.2.1).
	The storage of packaging outside is acceptable only where the packaging material:
	 is not at risk of deterioration (e.g. rusting of cans) is protected from contamination is cleaned effectively before filling.
	Once packing has finished, controls must be in place to ensure that any leftover packaging is still suitable for use before its return to storage (e.g. it has not been contaminated or printed with code information preventing re-use). Any open containers must be appropriately resealed or rewrapped and returned to appropriate storage to minimise the potential for contamination (such as splashing during cleaning operations) or mis-packs. The traceability of packaging should be retained (i.e. the coding is retained on the

outer packs on return to storage).

CLAUSE	REQUIREMENTS
4.15.3	Where temperature control is required (e.g. for raw materials, semi-finished materials or final products), the storage area shall be capable of maintaining product temperature within specification and operated to ensure specified temperatures are maintained. Temperature recording equipment with suitable temperature alarms shall be fitted to all storage facilities or there shall be a system of recorded manual temperature checks, typically on at least a 4-hourly basis or at a frequency which allows for intervention before product temperatures exceed defined limits for the safety, legality or quality of products.
Interpretation	Temperature control Where temperature control is required for the appropriate storage of products, the storage area must be capable of maintaining the required level. Good practice is for doors to close automatically or be alarmed to ensure they cannot be inadvertently left open.
	Temperature management is usually carried out through the use of automatic temperature-recording systems, which raise an alarm when temperatures fall outside a set range for a defined period (to allow for the usual defrost cycles). The alarm must be capable of notifying a responsible person outside of normal working hours, either by notification to on-site security, by a home call or by ringing through to a service centre.
	Where such automatic systems are not in use, the same level of safeguard to product temperature control needs to be instigated through manual temperature checks. To achieve a similar level of control, manual temperature checks should be carried out on a 4-hourly basis, including during nights and weekends. The frequency of checks could be reduced where the nature of the product and the insulating capability of the unit are such that the product would remain unaffected by a refrigeration failure of longer than 4 hours (e.g. some frozen products). Ongoing temperature records must demonstrate that product temperature requirements are being met.
	Procedures must specify the frequency of manual checks or the use of automatic continual monitoring systems. All temperature monitoring must allow intervention before product temperatures exceed defined limits for the safety, legality or quality of products.
4.15.4	Where controlled atmosphere storage is required, the storage conditions shall be specified and effectively controlled. Records shall be maintained of the storage conditions.
Interpretation	Storage in controlled atmosphere Where storage conditions include other parameters (e.g. modified atmosphere storage of fruit and vegetables), the mix of gases needs to be defined and monitored to ensure the quality of the product is managed. Tests are required to ensure that the correct composition of gases is present. They are different from the
4.15.5	tests identified in clause 4.5.3, which relate to contamination and food safety. Where storage outside is necessary, items shall be protected from contamination and deterioration.
Interpretation	Items shall be checked for suitability before being brought into the factory. Storage outside Where it is necessary to store product and equipment outside, they must be protected from pests and the elements. Particular attention must be paid to cleaning and inspection of the materials before they are brought into the factory and used, to prevent contamination.
4.15.6	The site shall facilitate correct stock rotation of raw materials, intermediate products and finished products in storage and ensure that materials are used in the correct order in relation to their manufacturing date and within the prescribed shelf life.
Interpretation	Stock rotation Stock, whether raw materials, intermediates (including rework) or finished products, must be controlled to ensure that materials are used in an appropriate order and do not exceed their shelf life. This control is generally operated on a 'first in, first out' basis.
	Product identification, such as labelling, and inventory systems can help to facilitate the correct order in relation to the materials' manufacturing dates and prescribed shelf life.

4.16 DISPATCH AND TRANSPORT

Procedures shall be in place to ensure that the management of dispatch and of the vehicles and containers used for transporting products from the site do not present a risk to the safety, security or quality of the products.

Interpretation

The site's procedures for dispatch and transport must be controlled to ensure they do not pose a risk to final products.

CLAUSE	REQUIREMENTS
4.16.1	Procedures to maintain product safety and quality during loading and transportation shall be developed and implemented. These may include, as appropriate:
	 controlling temperature of loading dock areas and vehicles the use of covered bays for vehicle loading or unloading securing loads on pallets to prevent movement during transit inspection of loads prior to dispatch.
Interpretation	Dispatch and transport procedures The site must consider the potential risks to product safety and quality that may develop during dispatch and transport. In addition to the points listed in the requirement, vehicles should also be inspected prior to loading and unloading (clause 4.16.2).
4.16.2	All vehicles or containers used for the transport of raw materials and the dispatch of products shall be fit for purpose. This shall ensure that they are:
	 in a clean condition free from strong odours which may cause taint to products in a suitable condition to prevent damage to products during transit equipped to ensure any temperature requirements can be maintained throughout transportation.
	Records of inspections shall be maintained.
Interpretation	Vehicle inspection Inspection of vehicles should be a site responsibility even where the vehicles and distribution are subcontracted. At a minimum, the inspection will cover whether vehicles have the correct levels of cleanliness and are free from evidence of pests and strong odours (which could taint a product), and have been maintained to prevent product damage during transit.
	The site should ensure that the correct operating temperatures are capable of being maintained throughout transportation (i.e. that the refrigeration temperature ranges remain within the permitted parameters). This may include pre-cooling trailers for temperature-sensitive products prior to loading, to maintain correct temperatures.
	Records of inspections must be maintained.
4.16.3	Where temperature control is required, the transport shall be capable of maintaining product temperature within specification, under minimum and maximum load. Temperature data-logging devices which can be interrogated to confirm time/temperature conditions or a system to monitor and record at predetermined frequencies the correct operation of refrigeration equipment shall be used and records maintained.
Interpretation	Vehicle temperature control Vehicles that are temperature-controlled must demonstrate the control of temperature under both minimum
	and maximum loads. This can be achieved through the use of temperature recorders, data loggers or manual recorded checks. Where manual checks are used, the frequency of checking must ensure that the safety and quality of the product are maintained. The use of data loggers may be considered as a monitoring method.
4.16.4	Maintenance systems and documented cleaning procedures shall be available for all vehicles and equipment used for loading/unloading. There shall be records of the measures taken.

CLAUSE	REQUIREMENTS
Interpretation	Vehicle maintenance and hygiene Documented hygiene and maintenance procedures for all vehicles (e.g. forklift trucks, pallet trucks) and equipment (e.g. loading hoses for silos) must be in place. They must include:
	 the method(s) of cleaning the frequency at which the cleaning must be completed records that the cleaning has been completed.
4.16.5	The company shall have procedures for the transport of products, which shall include:
	 any restrictions on the use of mixed loads requirements for the security of products during transit, particularly when vehicles are parked and unattended clear instructions in the case of vehicle breakdown, accident or failure of refrigeration systems, which
	ensure that the safety of the products is assessed and records maintained.
Interpretation	Transport procedures The site must have procedures for the transport of products. The procedures must include:
	 the identification of any restrictions for mixed loads (e.g. specifying where allergen-free materials are to be stored or transported) to avoid cross-contamination or taint uptake the security of all finished products in transport to ensure that they cannot be contaminated, either accidentally or deliberately. This may include tamper-evident packing, vehicle seals or contractual handling arrangements with transport providers (such as not leaving vehicles unattended in insecure situations) breakdown procedures for temperature-controlled vehicles (in case of, for example, vehicle breakdown
	or failure of the refrigeration system). These should consider: - facilities for vehicle drivers to easily contact the company or haulier for assistance - provision of a back-up vehicle or rapid-repair facility - guidelines to evaluate the acceptability of product affected by the breakdown.
	The appropriate staff must be trained in these procedures.
4.16.6	Where the company employs third-party contractors, all the requirements specified in this section shall be clearly defined in the contract or terms and conditions and verified, or the contracted company shall be certificated to the Global Standard for Storage and Distribution or similar GFSI-recognised scheme.
Interpretation	Third-party contractors An example of verification of third-party contractors and their compliance with the requirements of this section is by supplier audit.
	The use of terms and conditions for defining the requirements is an option where other forms of transport are used (e.g. couriers or larger-scale carriage such as rail transport).

5 PRODUCT CONTROL

5.1 PRODUCT DESIGN/DEVELOPMENT

Product design and development procedures shall be in place for new products or processes and any changes to product, packaging or manufacturing processes to ensure that safe and legal products are produced.

Interpretation

Procedures must be in place to ensure that all new product development and amendments to existing products result in safe products.

New product development or the introduction of new ingredients must not compromise existing activities or products handled in the same area; for example, the introduction of an allergen or microbiological risk that does not already exist in the area would need to be risk-assessed and managed to prevent contamination of existing products.

BRC Global Standards in collaboration with the Food and Drink Federation (FDF) and Campden BRI has published a guideline on migration from packaging materials into food, which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

CLAUSE	REQUIREMENTS
5.1.1	The company shall provide clear guidelines on any restrictions to the scope of new product developments to control the introduction of hazards which would be unacceptable to the site or customers (e.g. the introduction of allergens, glass packaging or microbiological risks).
Interpretation	New product development The objective of this clause is to ensure that product development activities are aligned with any site policies on the types of product or hazards handled on site, to prevent the introduction of these hazards. Typically, this applies where companies have policies to exclude particular allergens (e.g. nuts) from the site. Any such restrictions must be documented. Where no restrictions apply, this need not be documented.
5.1.2	All new products and changes to product formulation, packaging or methods of processing shall be formally approved by the HACCP team leader or authorised HACCP committee member. This shall ensure that hazards have been assessed and suitable controls, identified through the HACCP system, are implemented. This approval shall be granted before products are introduced into the factory environment.
Interpretation	Approval of HACCP for new products It is important that the site understands the product safety rationale for all new products (i.e. the criteria that make a product safe for consumption). This may, for example, include processing conditions such as cooking or temperature control; intrinsic properties of the product such as pH or water activity; control of shelf life; or the effect of specific ingredients such as preservatives.
	Experience has shown that sometimes even minor changes to ingredients, packaging or processing conditions can have a significant effect on the safety of products. The sign-off of changes by the HACCP team leader or an authorised HACCP team member is designed to ensure that the consequences of any change are understood. Therefore a full description of each proposed change to a product, raw material or process must be made available to the HACCP team. This can be demonstrated by a record of the sign-off of product changes (e.g. a change authorisation form).
	Records should be available even where the change does not result in any modification to the existing HACCP or food safety plan.
	The assessment of any potential impact on product safety and subsequent sign-off must occur before the products are introduced into the factory; i.e. sign-off must be completed before factory trials begin to ensure that new risks (e.g. from allergens) are not introduced into the factory without suitable controls approved by the HACCP team.
5.1.3	Trials using production equipment shall be carried out where it is necessary to validate that product formulation and manufacturing processes are capable of producing a safe product of the required quality.

CLAUSE	REQUIREMENTS
Interpretation	Factory trials Documented evidence of production trials (i.e. not kitchen-scale trials) needs to be available, together with test results validating that the product formulation and manufacturing processes are capable of producing a safe product of the desired quality.
	Factory trials may not be required where new products are very closely based on existing products. Where production trials are not undertaken, the reason must be documented.
5.1.4	Initial shelf-life trials shall be undertaken using documented protocols that reflect conditions expected during manufacture, storage, transport/distribution, use and handling to determine product shelf life.
	Results shall be recorded and retained and shall confirm compliance with the relevant microbiological, chemical and organoleptic criteria/sensory analysis. Where shelf-life trials prior to production are impractical, for instance for some long-life products, a documented science-based justification for the assigned shelf life shall be produced.
Interpretation	Initial shelf-life evaluation The company must establish a documented procedure detailing how initial shelf-life trials are undertaken for new products and changes to existing products. This procedure must consider the handling conditions throughout the supply chain (e.g. chilled products are often subject to 2 hours at an ambient temperature mid-life to mimic the conditions during retail shopping). The aim of shelf-life trials is to confirm that product safety, legality and quality are acceptable throughout the expected shelf life.
	Samples to determine the shelf life should be taken from the trials detailed in clause 5.1.3. Where long-shelf-life products (e.g. some canned or frozen products) are developed, it may not be possible to complete full shelf-life trials. The justification for the declared shelf life must be documented and based on experience from similar products and science-based evidence.
	Where rework is used or work in progress is stored, shelf life of the material should be established to ensure it is used within the correct period.
	Ongoing verification of shelf-life is covered separately in clause 5.6.1.3.

5.2 PRODUCT LABELLING

Product labelling shall comply with the appropriate legal requirements and contain information to enable the safe handling, display, storage and preparation of the product within the food supply chain or by the customer.

Interpretation

The labelling of products must meet all of the legal requirements for the designated country of use. The site must therefore have processes to ensure it remains up to date with labelling requirements in that country (or countries) and that these requirements are accurately transferred onto the packaging and labels.

For the purposes of the Standard, the following definitions apply:

- label any tag, mark, picture or other descriptive matter, whether it is written, printed or otherwise marked, on or attached to the packaging of the product
- labelling any words, picture or symbol relating to the food and placed on any packaging or label accompanying the product.

CLAUSE	REQUIREMENTS
5.2.1	All products shall be labelled to meet legal requirements for the designated country of use and shall include information to allow the safe handling, display, storage, preparation and use of the product within the food supply chain or by the customer. There shall be a process to verify that ingredient and allergen labelling is correct based on the product recipe and ingredient specifications.

CLAUSE REQUIREMENTS

Interpretation

Legality of labels

The site's procedures must include the completion of a legality check and sign-off of the proofs (or draft designs) of new labels to ensure their compliance; this will include verification of ingredient and allergen information, based on both the product recipe and ingredient specifications. The appropriate legislative requirements in the country (or countries) in which the products will be used must be considered.

During the vertical audit, the BRC Global Standards auditor will assess the site's processes for ensuring the accuracy of labelling and verify that the systems are operating correctly. The auditor will not check every aspect of the labelling to confirm its legality but will select samples of on-pack information for the site to substantiate. For example:

- for a product which claims '10% meat', the auditor may ask for the evidence that demonstrates this claim. This may include the product recipe, the mass balance exercise for the specific batch etc.
- for a product which claims to be a 'product of the UK', demonstration of the accuracy of the claim could include evidence of the origin of the materials purchased from suppliers
- the auditor may compare the on-pack ingredient information with the recipe and specification.

5.2.2

There shall be effective processes in place to ensure that labelling information is reviewed whenever changes occur to:

- the product recipe
- raw materials
- the supplier of raw materials
- the country of origin of raw materials
- legislation.

Interpretation

Label review

The accuracy of product labelling is of primary importance for the legality, consumer safety and the maintenance of product integrity. It is therefore important that whenever a change occurs to the product, its formulation or the ingredients, there is a review of the label information to ensure it remains correct and up to date. Where it is not, this must lead to a change in the labelling. Reviews, for example, will be required when there are changes to the:

- product recipe (e.g. reformulation of an existing product)
- composition of the raw materials. For example, when the recipe of a bought-in compound raw material changes, good practice is for the supplier to notify the site of the proposed change before it actually occurs. This should be documented in the supplier approval process (section 3.5)
- supply chain (e.g. the introduction of new suppliers of raw materials)
- legislation
- country of origin of the product or ingredients.

5.2.3

Where a product is designed to enable a claim to be made to satisfy a consumer group (e.g. a nutritional claim, reduced sugar), the company shall ensure that the product formulation and production process are fully validated to meet the stated claim.

Interpretation

Nutritional claims

Where a particular claim about the formulation of a product has been made, procedures must be in place to validate that the claim is correct and to ensure that, when handling the product during processing, contamination or variation which adversely affects the claim cannot occur. A procedure might, for example, include completing a nutritional analysis which can be checked against the proposed product labelling and specification.

Good practice is to ensure that a programme of ongoing verification is in place to demonstrate that claims are consistently being met. Claims such as 'free from' and 'allergen-free' need particular care to ensure that cross-contamination cannot occur during processing. This is covered separately in clause 5.3.7.

Where there are particular legislative requirements relating to claims such as low fat, sugar or salt, the requirements must be understood and met.

CLAUSE	REQUIREMENTS
5.2.4	Where the label information is the responsibility of a customer or a nominated third party, the company shall provide information:
	 to enable the label to be accurately created whenever a change occurs which may affect the label information.
Interpretation	Third-party label design This clause is applicable wherever the decision on pack copy is not controlled by the company but is the responsibility of the customer or a nominated third party.
	In these circumstances the site is responsible for supplying accurate information on which to base the label creation. A system must therefore be in place to transfer all the relevant initial information to the customer and for ensuring that any changes are communicated in a timely manner.
5.2.5	Where cooking instructions are provided to ensure product safety, they shall be fully validated to ensure that, when the product is cooked according to the instructions, a safe, ready-to-eat product is consistently produced.
Interpretation	Cooking instructions This clause is concerned with cooking instructions that are required to make a product safe to eat when cooked (e.g. products containing raw chicken). The site must validate that the cooking instructions will result in a product that is consistently safe to eat when the instructions are followed. Sites should also consider the potential for instructions to be deviated from.
	If sites are using cooking instructions in connection with products assessed as high risk or high care, they should refer to Appendix 2 in the Standard.

5.3 MANAGEMENT OF ALLERGENS

FUNDAMENTAL

The site shall have a system for the management of allergenic materials which minimises the risk of allergen contamination of products and meets legal requirements for labelling in the country of sale.

Interpretation

Legislation in many countries requires that the presence of food allergens, when deliberately present in a product, must be declared on the pack.

Leaving aside the deliberate use of allergenic ingredients in a food, there are occasions when a product can be cross-contaminated because of the supply chain or manufacturing environments. Where there is a genuine risk of cross-contamination with an allergen, this must be managed to minimise both its likelihood and the levels of allergen that are likely to be present.

The specific legislative requirements in the geographic origin of the raw material, in the country of manufacture and in the country of sale must be considered. This is necessary to ensure that all the relevant allergens are managed and none is inadvertently omitted because of differences in the legislation. For example, the list of substances that are considered to be allergenic is different in Europe, the US, Australia and Japan.

Where products are both produced and sold in countries where there are no legal requirements for the labelling of allergens, the list of allergens as defined in the Codex General Standard for the Labelling of Prepackaged Foods (Codex Stan 1-1985, paragraph 4.2.1.4) should be used as the basis for assessing compliance with the Standard.

Research is being conducted in a number of countries, including the UK and Australia, to identify allergen thresholds (i.e. the minimum amount of an allergen that will cause a reaction in the majority of allergic customers). This research may, in due course, provide useful data that can be combined with other risk assessment tools. At the current time, however, this data has not been fully evaluated. Even though early indications are that the values will be very low (e.g. a few milligrams), factories must continue to use the full range of risk assessment and management tools to ensure they produce products that are safe for allergic consumers.

BRC Global Standards publishes a separate guideline on allergen management, which may be purchased from the BRC Global Standards bookshop (**www.brcbookshop.com**) or viewed online at BRC Participate (**www.brcparticipate.com**).

CLAUSE	REQUIREMENTS
5.3.1	The site shall carry out an assessment of raw materials to establish the presence and likelihood of contamination by allergens (see glossary). This shall include a review of the raw material specifications and, where required, the acquisition of additional information from suppliers (e.g. through questionnaires to understand the allergen status of the raw material, its ingredients and the factory in which it is produced).
Interpretation	Raw material assessment Raw materials are a potential source of allergens and of cross-contamination. Therefore, the supplier approval and raw material risk assessment procedures (section 3.5.1) must include an assessment of raw materials for the presence of allergens and the potential for cross-contamination.
	Raw material specifications (including flavourings, additives, carriers and processing aids) must be agreed with each raw material supplier and include the allergen status (both content and risk of cross-contamination) of the materials.
	Where required, additional allergen information must be obtained (e.g. through the use of supplier questionnaires or audits).
	Where a compound raw material (i.e. one manufactured from a number of ingredients) is purchased, the risk assessment must consider the risks associated with the raw material, its ingredients and the manufacturing sites of the ingredients. The assessment process and the outcome of the assessment must be documented.
5.3.2	The company shall identify and list allergen-containing materials handled on site. This shall include raw materials, processing aids, intermediate and finished products, and any new product development ingredients or products.
Interpretation	List of allergenic materials The aim of this clause is to ensure that the site maintains up-to-date knowledge of the allergens that are handled on the site. It is therefore important that the allergen status of all raw materials, additives, processing aids, intermediates and final products are known, both in terms of the deliberate presence of allergens and the potential for cross-contamination.
	All materials that contain allergenic substances (ingredients, processing aids, intermediates and finished products) must be listed in a single reference document. This might also include non-food materials used in production areas (e.g. pest control baits that are wheat-based).
	The need to maintain an up-to-date list should be communicated to all areas of the company which can introduce new allergens onto the site (e.g. new product development or engineering).
5.3.3	A documented risk assessment shall be carried out to identify routes of contamination and establish documented policies and procedures for handling raw materials and intermediate and finished products to ensure cross-contamination (cross-contact) is avoided. This assessment shall include:
	 consideration of the physical state of the allergenic material (i.e. powder, liquid, particulate) identification of potential points of cross-contamination (cross-contact) through the process flow assessment of the risk of allergen cross-contamination (cross-contact) at each process step identification of suitable controls to reduce or eliminate the risk of cross-contamination (cross-contact).
Interpretation	Risk assessment for cross-contamination A risk assessment process must be completed to identify potential routes of cross-contamination (cross-contact). Consideration must be given to:

- the physical state of the allergen. For example:
 - powdered ingredients represent a greater risk of aerial cross-contamination than those in liquid form
 - $\ \ \text{sticky or fatty ingredients are likely to adhere to surfaces should cleaning be ineffective}$
 - particulates (such as pieces of nut) may result in significant heterogeneous contamination

CLAUSE

REQUIREMENTS

- the identification of potential points of cross-contamination. An 'allergen process flow diagram' or 'allergen map' can be useful in understanding where allergenic ingredients and foods exist in the plant and where they are introduced into the process. This usually takes the form of a site plan on which are highlighted all the routes each allergenic material can take. This map can subsequently be used to identify areas where cross-contamination between allergenic and non-allergenic materials (ingredients, intermediates or products) can occur. (The map should consider process flow, environmental factors, production activities, shared equipment and people.)
- an assessment of the risk at each stage identified in the previous step
- the identification and implementation of all reasonable controls to reduce or eliminate cross-contamination (e.g. segregation, the use of dedicated lines or equipment, enhanced cleaning schedules).

The risk assessment process, the assessments and any resulting procedures or factory controls must be documented.

5.3.4

Procedures shall be established to ensure the effective management of allergenic materials to prevent cross-contamination (cross-contact) of products not containing the allergen. These shall include, as appropriate:

- physical or time segregation while allergen-containing materials are being stored, processed or packed
- the use of separate or additional protective overclothing when handling allergenic materials
- use of identified, dedicated equipment and utensils for processing
- scheduling of production to reduce changes between products containing an allergen and products not containing the allergen
- systems to restrict the movement of airborne dust containing allergenic material
- waste handling and spillage controls
- restrictions on food brought onto site by staff, visitors and contractors and for catering purposes.

Interpretation

Cross-contamination procedures

The risk assessment (clause 5.3.3) must be used to develop the factory controls and procedures for handling raw materials, intermediates and finished products to reduce (and, where possible, remove) the risk of cross-contamination. All allergens present on site must be considered so that procedures can be designed to prevent cross-contamination with each specific allergen. For example, contaminating an allergen-containing product with another allergen (such as contaminating a nut-containing product with milk) is just as significant as contaminating a product with no allergens with that allergen.

Procedures must be implemented even where on-pack warning labels (clause 5.3.6) are used. Particular attention should be given to:

- physical segregation. Ideally, allergenic ingredients and products will be totally segregated from non-allergenic ingredients and products. This could involve, for example, dedicated storage areas, dedicated (and colour-coded) production equipment, and the use of dedicated production lines
- time segregation. Where products must be handled in the same factory areas or on the same production lines, consideration should be given to the use of time segregation. For example, all non-allergenic products could be produced first and allergenic materials introduced subsequently, or the use of allergenic materials could be confined to the end of a day/shift and only before a full clean. Production scheduling could also be used to minimise the frequency of changeovers between allergen-containing and non-allergen-containing products. For example, in some factories it is possible to limit the use of nuts to a defined period or shift, rather than producing nut-containing products throughout the week
- the potential for protective clothing to be a source of allergen contamination. The use of separate clothing
 or overalls for handling allergenic materials should be considered. It is normally useful to colour-code
 protective clothing to prevent confusion
- the use of dedicated equipment or utensils. These should be clearly identifiable (e.g. by colour-coding)
- allergens that can form fine powders (e.g. flour, milk powder and soya isolates). The movement of
 airborne dust should be minimised by, for example, using physical barriers (such as shrouds, lids or
 segregated areas) for dispensing and mixing operations. The location of air-conditioning outlets or the
 use of fans should also be considered to ensure these do not distribute airborne allergens

CLAUSE **REQUIREMENTS** waste-handling and spillage controls. Allergens should be removed efficiently, ensuring that the removal process does not become the source of allergen contamination in other areas of the factory • the allergens that may be handled in non-production areas of the site (e.g. in canteens or in new product development). A policy for food brought on site by staff, or used in vending machines or catering facilities, should be developed. The policy may ban certain allergens or restrict them to certain areas of the site. Where colour-coding is used, consideration must be given to the choice of colours to ensure that colour-blind staff are able to identify the correct items. Where rework is used, or reworking operations are carried out, procedures shall be implemented to ensure 5.3.5 rework containing allergens is not used in products that do not already contain the allergen. Interpretation Rework Specific documented procedures must operate to prevent rework containing allergens from being used in products or processes that do not contain those allergens. Best practice is for rework to be used on a 'like-for-like' basis (i.e. it is used only in exactly the same product). The use of rework must be documented. Where a justified, risk-based assessment demonstrates that the nature of the production process is such 5.3.6 that cross-contamination (cross-contact) from an allergen cannot be prevented, a warning should be included on the label. National guidelines or codes of practice shall be used when making such a warning statement. Interpretation On-pack warning labels Where controls cannot prevent cross-contamination (cross-contact) and there is a significant and genuine risk of the presence of an allergen that would not otherwise be present and is therefore not mentioned elsewhere on the product (e.g. in the ingredients list), the use of on-pack advisory labels should be considered. The use of a warning label should be justifiable on the basis of the risk assessment (clauses 5.3.3 and 5.3.4) and should not be a substitute for good manufacturing practices. Reference must be made to national legislation, guidelines or codes of practice when making such a statement to ensure that best practice is followed. For example, consideration should be given to: • the location of the warning (preferably in close proximity to the ingredients list) • the visibility of the statement - colour, highlighting, location and font size can all aid consumers • the choice of the warning phrase used, so that the meaning is clear to consumers. Where a claim is made regarding the suitability of a food for allergy or food sensitivity sufferers, the site shall 5.3.7 ensure that the production process is fully validated to meet the stated claim and the effectiveness of the process is routinely verified. This shall be documented. Interpretation Allergen claims Allergic, food-intolerant or sensitive individuals are likely to actively seek and choose products that claim to be suitable for them to consume (e.g. 'gluten-free' products). It is therefore essential that any allergen claim is based on rigorous controls to ensure its validity and continuous implementation. Where a claim is made regarding the suitability of a food, full validation and verification activities will be required to ensure that the claim is consistently met. Typically, this will include: demonstration that production processes are in place to ensure the product does not contain traces of the allergen • analysis of the final product assessment of the adequacy of cleaning, as detailed in clause 5.3.8 (where the site also produces products containing the allergen about which the claim is made, additional verification controls will be required) raw material controls. In addition to the normal requirements listed in clause 5.3.1, additional validation/ verification requirements are likely to be needed (e.g. raw material testing, additional supplier questionnaires, site audits). The validation and verification activities must be recorded.

CLAUSE	REQUIREMENTS
5.3.8	Equipment or area-cleaning procedures shall be designed to remove or reduce to acceptable levels any potential cross-contamination (cross-contact) by allergens. The cleaning methods shall be validated to ensure that they are effective and the effectiveness of the procedure routinely verified. Cleaning equipment used to clean allergenic materials shall either be identifiable and specific for allergen use, single use, or effectively cleaned after use.

Interpretation

Allergen cleaning regimes

Some standard cleaning regimes will be insufficient to ensure the removal of all allergenic material. Therefore, specific cleaning procedures must be present on site where allergen-containing materials require control.

Cleaning procedures must be designed to remove or reduce to acceptable levels any allergenic material. They must consider:

- cleaning schedules (i.e. when cleaning will be completed)
- scheduling sufficient time to fully complete the clean to the required standard
- ensuring that cleaning instructions contain all the information required
- the order in which cleaning must be performed (to ensure that cleaning does not move an allergen into a previously cleaned area)
- the cleaning equipment used for cleaning allergenic materials, which must not be a source of contamination and must therefore be either dedicated for the removal of that allergen, single use or effectively cleaned after use.

Where multiple allergens are handled on site, consider whether all allergens could be managed by the same cleaning/validation/verification activities. For example, peanuts, milk and sesame seeds may need different controls because of their different physical characteristics. They may also be used on different equipment and production lines, again requiring separate consideration.

The effectiveness of the procedures must be validated. The validation must be documented and evidence will typically include:

- worst-case production/cleaning trials, where all equipment, processes and allergens need to be considered
- targeted test locations, such as food contact surfaces, difficult-to-clean areas, deadlegs etc.
- targeted samples, where worst-case samples are identified for laboratory testing using suitably sensitive
 test methods. (Validation tests should be accredited methods and, wherever possible, quantifiable.
 Rapid tests, ATP and lateral flow devices are good for verification activities but are not suitable for
 validation.) Possible samples include the first product manufactured in the next production run, rinse
 water from cleaning systems, swabs etc.
- assessment of new equipment for ease of cleaning prior to purchase
- positive testing of the test method used, to confirm that it will detect the allergen if it is present in a real sample (i.e. confirmation that product matrix will not interfere with the test).

It is likely that validation data will need to be collected from several production runs to ensure it is representative and complete. A number of best-practice guidelines have been published on the validation of cleaning (e.g. Campden BRI Guideline 59 – Validation of Cleaning to Remove Food Allergens).

The cleaning procedures must be routinely verified by, for example:

- visual inspections and documented sign-off
- inclusion in internal audits
- the use of swabs or testing (e.g. rapid tests, ATP, lateral flow devices or laboratory tests).

Records must be maintained of validation and verification checks and activities. Any corrective actions must also be recorded and completed.

BRC Global Standards has a training course on validation and verification. Further information is available from **www.brctrainingacademy.com**.

5.4 PRODUCT AUTHENTICITY, CLAIMS AND CHAIN OF CUSTODY

Systems shall be in place to minimise the risk of purchasing fraudulent or adulterated food raw materials and to ensure that all product descriptions and claims are legal, accurate and verified.

Interpretation

The objectives of this section of the Standard are to ensure:

- the site has assessed its raw materials and supply chain for vulnerability to food fraud activities such as the dilution or substitution of ingredients prior to delivery to the site
- the site has appropriate controls in place (based on the assessment) to minimise the risk of purchasing fraudulent or adulterated raw materials
- all claims relating to raw materials used in products can be substantiated and that the BRC Global Standard audit provides a suitable evaluation of the site's management of the chain of custody, where claims are made relating to primary agricultural schemes such as GlobalG.A.P.

CLAUSE	REQUIREMENTS
5.4.1	The company shall have processes in place to access information on historical and developing threats to the supply chain which may present a risk of adulteration or substitution of raw materials (i.e. fraudulent raw materials). Such information may come from, for example:
	trade associationsgovernment sourcesprivate resource centres.
Interpretation	Provision of knowledge and information Information relating to the adulteration or substitution of raw materials constantly changes as new risks are identified and existing ones are managed. The objective of this clause is therefore to ensure that sites remain up to date with emerging issues and are able to adapt their systems to protect their products against new and existing risks to the integrity of their products.
	The company must be able to demonstrate that it maintains up-to-date knowledge of relevant scientific and technical developments, emerging issues and known risks relating to the authenticity of the raw materials it purchases and the potential for food fraud in the supply chain. Mechanisms to achieve this may include:
	 membership of a trade association which provides this service help from government officials or local enforcement offices subscription to a service provider supplying updates on food fraud.
	The auditor will look for evidence of systematic checking and a process for ensuring the information is transferred into action as necessary (clause 5.4.2).
	Information may be obtained and collated as part of the provision of technical knowledge (clause $1.1.8$) or as a separate exercise, providing it is clear that relevant information is being obtained.
5.4.2	A documented vulnerability assessment shall be carried out on all food raw materials or groups of raw materials to assess the potential risk of adulteration or substitution. This shall take into account:
	 historical evidence of substitution or adulteration economic factors which may make adulteration or substitution more attractive ease of access to raw materials through the supply chain sophistication of routine testing to identify adulterants the nature of the raw material.
	The output from this assessment shall be a documented vulnerability assessment plan. This plan shall be kept under review to reflect changing economic circumstances and market intelligence which may alter the

potential risks. It shall be formally reviewed annually.

CLAUSE

REQUIREMENTS

Interpretation

Vulnerability assessment

A vulnerability assessment is a search for potential weaknesses in the supply chain in order to prevent food fraud (i.e. to prevent the adulteration or substitution of raw materials before they arrive at the site). It is a specialised form of risk assessment. The aim of the assessment is not to assess the potential for fraud at the site, but to examine the supply chain for potential concerns or weaknesses, thereby identifying those raw materials that are at particular risk of adulteration or substitution, so that appropriate controls can be put in place (clause 5.4.3).

The vulnerability assessment will consider information relating to each ingredient in order to assess whether there is a potential for food fraud. Where a site purchases a number of similar raw materials, it may be possible to consider these as a group rather than each raw material individually, providing the risks are similar.

Typical information to incorporate into the assessment includes:

- any emerging issues and information identified in clause 5.4.1
- historical evidence of substitution or adulteration of the ingredient
- cost/value of the material
- availability (e.g. a poor harvest may restrict availability and may increase the potential for adulteration)
- sophistication of routine testing to identify adulterants. If testing within the supply chain is comprehensive and specifically focused on potential fraud issues, then the likelihood of adulteration is reduced (e.g. fruit juice is often tested for a comprehensive range of parameters, including DNA, isotopic analysis, added sugars and added water to prevent potential fraud)
- country of origin
- length and complexity of the supply chain
- supply chain model
- controls that are already in the supply chain. For example, if the raw material supplier is certificated to
 the Standard, then as part of that certification the supplier must have completed its own vulnerability
 assessment, and there is no requirement in the Standard for the site to duplicate its supplier's
 vulnerability assessment.

The nature of the raw material may change the potential for food fraud. For example, if a slaughterhouse is purchasing cattle, horses and pigs for slaughter, it will be obvious if there is an issue with the live animals; however, if the slaughterhouse intends to make a claim such as organic, Aberdeen Angus or specified country of origin, then greater controls of raw materials will be required to ensure only those which meet the claim are purchased. Similarly, prepared ingredients such as beef mince or ground spices are likely to have a greater risk than the whole ingredient.

The Standard does not define the exact process that the site must follow when completing the vulnerability assessment; however, it is likely to incorporate the following steps:

- draw up a list of raw materials (or groups of raw materials) and the controls (e.g. product testing, traceability systems or supply chain audits) that are already in operation
- consider the information obtained from clause 5.4.1 for each ingredient
- complete a risk assessment on the vulnerability of each ingredient.

Note that the Standard does not require full supply chain mapping for all raw materials, although this may be a useful tool where a risk assessment indicates that a genuine risk exists and there is a need to identify the point in the supply chain where an effective control can be applied.

The output of the vulnerability assessment must include a documented vulnerability assessment plan which should rank or score the materials to identify those which need additional controls. The ranking and actions required could, for example, be as follows:

- **Very high** A high-profile raw material with recent reports of adulteration published by regulatory authorities. Action or monitoring is required to ensure only genuine materials are purchased
- **High** A high-profile material that provides an attractive target for potential adulteration. Some action and/or monitoring is required to ensure only genuine materials are purchased

CLAUSE **REQUIREMENTS**

- Low This material is unlikely to be a target for substitution or adulteration; however a re-assessment may be necessary if new information becomes available
- **Negligible** No further action required as the material is extremely unlikely to be a target for food fraud.

It is important that the vulnerability assessment remains up to date and it must be reviewed at least annually or when there is a significant change to the ingredient. As a guide, a review may be triggered by the following, although this is not an exhaustive list:

- a change in the country of origin or the supplier of raw materials
- a change in the financial situation of raw material suppliers or countries of origin
- a change in cost of raw materials, either upwards or downwards
- a change in the supply chain, logistics and delivery of materials
- a change in material availability (e.g. because of seasonal shortages)
- emergence of a new risk (e.g. known adulteration of an ingredient)
- developments in scientific information associated with ingredients, process or product
- information received as part of a supplier approval or raw material risk assessment (e.g. clause 3.5.1.1) which highlights new or evolving risks.

A number of risk assessment tools have been published. These include some specialist vulnerability assessment tools such as CARVER + Shock and TACCP (threat assessment and critical control points), which may be used to achieve a structured approach to the assessment process.

BRC Global Standards has published a number of items to assist with vulnerability assessments. These include a specific vulnerability assessment quideline that can be obtained from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com). A training course is available through the BRC Global Standards training academy and its global network of approved training providers (ATPs).

5.4.3

Where raw materials are identified as being at particular risk of adulteration or substitution, the vulnerability assessment plan shall include appropriate assurance and/or testing processes to mitigate the identified risks.

Interpretation

Output from the vulnerability assessment

Where raw materials are identified as being of particular risk of adulteration or substitution, appropriate assurance controls need to be in place to ensure that only genuine materials are purchased. Depending on the perceived risk, assurance controls may include:

- certificates of analysis from raw material suppliers
- raw material testing
- supply chain audits
- use of tamper evidence or seals on incoming raw materials
- enhanced supplier approval checks
- mass balance exercises at the raw material supplier
- changes to the supply chain (e.g. a change of supplier or a move to a shorter supply chain).

It is worth noting that the best controls are proactive and continuous as these are the most likely to prevent an incident from occurring. For example, product testing is a useful tool but it is reactive (i.e. it can only tell you if something has happened; it cannot prevent it from occurring or recurring in future).

5.4.4

Where products are labelled or claims are made on finished packs which are dependent on the status of a raw material, the status of each batch of the raw material shall be verified. These claims include:

- specific provenance or origin
- breed/varietal claims
- assured status (e.g. GlobalG.A.P.)
- genetically modified organism (GMO) status
- identity preserved
- named specific trademarked ingredients.

The facility shall maintain purchasing records, traceability of raw material usage and final product packing records to substantiate claims. The site shall undertake documented mass balance tests at a frequency to meet the particular scheme requirements or at least every 6 months in the absence of a scheme-specific requirement.

CLAUSE

REQUIREMENTS

Interpretation

Status verification of raw materials

The types of claim covered by this clause relate to the provenance of ingredients used in a product that differentiates those ingredients or product from the norm. Such a claim may be made either on the product label for the consumer or in business-to-business communication. The types of claim include:

- varietal claims (e.g. basmati rice, Aberdeen Angus beef, Bramley apples and cod fish cakes)
- origin claims (e.g. Madagascan vanilla and Florida grapefruit)
- assurance claims (e.g. GlobalG.A.P., Red Tractor, Marine Stewardship, dolphin-friendly tuna and sustainable palm oil)
- identity-preserved claims (e.g. GMO (genetically modified organism) free).

Claims which relate to the composition of the product (e.g. nutritional claims, fat-free, reduced sugar, free-from etc.) are covered in clauses 5.2.3 and 5.3.7.

It is the responsibility of the site to make reasonable checks to ensure that the raw materials supplied are genuine and that claims made about ingredients are proven.

For many assurance schemes, such as GlobalG.A.P., it is possible to check the assurance status and the scope of products of the supplier on a database. Reliance solely on a declaration from a supplier will not be sufficient. Where claims relate to variety or species (e.g. varieties of fruit), examination of visual characteristics may suffice. However, for claims where visual analysis is not possible (e.g. block frozen fish), certificates of analysis and periodic sample analysis will be required.

Full traceability records must be maintained, as required in section 3.9. The records must also include details of the quantities purchased and amounts used at each step to enable a mass balance exercise to be undertaken.

In the absence of more frequent requirements relating to a particular scheme, the site must undertake a mass balance traceability exercise on typical products for which the claim is made at least every 6 months. This must ensure that the system of records maintained enables all finished product batches to be identified for a particular batch of raw materials and that, for a given finished product, the batch(es) of raw materials used for its production can be identified. The test must be carried out in both directions.

The ingredients selected for the mass balance exercise must include the ingredient for which a claim is made. The objective is to test the systems and, where necessary, make improvements to information recording to allow claims to be substantiated should they be challenged by a customer or legal authority.

It follows that, where very different traceability systems are used within, for example, a complex or multi-product site, more than one mass balance traceability exercise may be required every 6 months to ensure that all systems are working effectively. However, where a site has multiple claims, it is not intended that every claim be mass balance tested every 6 months but that a representative selection of claims are chosen. In this situation, good practice would be to choose different claims or products each time the test is conducted.

The use of a third-party mass balance exercise (e.g. by an organic certifier or by the Fairtrade Foundation) would be acceptable evidence of a test, providing that records of the test, the results and evidence of any necessary improvements made as a result of the test are maintained.

Where the third-party scheme measures the mass balance over a period (e.g. 1 month) rather than for a single batch code this is considered acceptable providing the requirements discussed above are met. If, as part of the requirements for a particular scheme or to use a logo, there is a requirement for more frequent mass balance traceability exercises, then that scheme's requirements must be met.

5.4.5

Where claims are made about the methods of production (e.g. organic, halal, kosher) the site shall maintain the necessary certification status in order to make such a claim.

Interpretation

Certificated third-party standards

Where a site wishes to make claims relating to specific production methods, such as organic, Halal or Kosher, the site is responsible for maintaining the appropriate certification to those standards.

While the accuracy of the production methods relating to these third-party certification standards will not be assessed during a BRC Global Standard audit, the auditor will require evidence that the appropriate certification is in place (e.g. by reviewing the certificate or an online database of certificated sites).

CLAUSE	REQUIREMENTS
5.4.6	The process flow for the production of products where claims are made shall be documented and potential areas for contamination or loss of identity identified. Appropriate controls shall be established to ensure the integrity of the product claims.
Interpretation	Preventing mixing or loss of identity The process flow diagram used within the HACCP process may be used as the basis for demonstrating compliance with this clause (the requirement may already be covered within the HACCP or food safety plan). The site must identify (e.g. as a list or on the process flow) potential areas where mixing of products or loss of identity may occur. Procedures of working or changes in process flow must be introduced to reduce the risk of mistakes and false claims being made.
	For example, in a large packhouse packing both farm-assured and non-farm-assured fruit, the farm-assured fruit is always stored separately within dedicated cold stores. Grading and packing operations are organised so that the packing of farm-assured product occurs first or on particular packing lines.

5.5 PRODUCT PACKAGING

Product packaging shall be appropriate for the intended use and shall be stored under conditions to prevent contamination and minimise deterioration.

Interpretation

Consideration of packaging is crucial for ensuring the ongoing integrity of the product (i.e. ensuring it is clean and of the appropriate quality) and in maintaining product safety and legality.

CLAUSE	REQUIREMENTS
5.5.1	When purchasing or specifying primary packaging, the supplier of packaging materials shall be made aware of any particular characteristics of the food (e.g. high fat content, pH, usage conditions such as microwaving, other packaging used on the product) which may affect packaging suitability. Certificates of conformity or other evidence shall be available for primary packaging to confirm it complies with applicable food safety legislation and is suitable for its intended use.
Interpretation	Compliance with legislative requirements There have been incidences of product recalls which have resulted from a lack of communication between the supplier of the packaging materials and the food manufacturer, typically where a packaging material has been used in extreme product conditions or where packaging not designed for direct food contact has been used (e.g. a plastic liner of a carton is removed or changed to reduce costs).
	The company must be able to demonstrate that each item of product packaging meets legal requirements for its use (e.g. compliance with food contact regulations in the country of sale). This may be in the form of specifications, migration data or a certificate of conformity. Where a declaration of conformity is used, any limitations on usage must be stated (e.g. the food types or storage conditions: ambient, chilled or frozen).
	The supplier of the packaging must be made aware of the conditions under which the packaging is going to be used, so that the suitability of the packaging materials can be confirmed. This may take the form of a specification provided to the packaging supplier and would include, as appropriate:
	 contact with food – direct food contact or, where not used for direct food contact, the nature of the barrier layer characteristics of the food – any adverse characteristics of the food which may increase migration of chemicals from the packaging (e.g. high fat content, or low or high product pH) conditions of processing (e.g. high-temperature fill, thermal processing in pack, or freezing) expected customer usage (e.g. microwave in pack, cooking in pack, or freezing).
	Direct food contact materials are of most concern as these have the greatest potential for harm and many geographical regions have specific legislation around direct contact packaging. However, there may be risk associated with the additional layers of packaging, particularly labelling which often comprises the primary

pack (consumer unit) and also secondary packaging such as corrugated cases. Physical or chemical

contamination can occur from these packaging components.

CLAUSE **REQUIREMENTS** Discussions with the provider of packaging materials are imperative to ensure that the right materials in the right configurations are used (e.g., using lower levels of recycled content in a corrugated case for products that are susceptible to chemical migration). Extensive work at the start of the process is incredibly valuable and can prevent costly errors from being made in specifications. It is also vital to consider the product supply chain to establish the most appropriate packaging, given the storage and distribution conditions that the product will be subjected to. BRC Global Standards has published a quideline on migration from packaging materials into food which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com). Product liners and bags purchased by the company for use in direct contact with ingredients, or work in 5.5.2 process, shall be appropriately coloured (e.g. contrasting colour to the product) and resistant to tearing to prevent accidental contamination. Interpretation **Product contact liners** Materials used as liners for containers, as covers for work in progress or as bags for prepared ingredients may themselves be a source of contamination. Such packaging materials must be visually distinct from the product (e.g. blue or red) and of a sufficient thickness to reduce the potential for ripping or being damaged. Good practice is to ensure that bag and film gauges are documented and communicated to suppliers to ensure that only suitable materials are purchased. The requirement applies only to materials purchased by the site and used on site; it does not apply to finished product packing. However, suppliers of raw materials should be strongly encouraged to supply ingredients in accordance with this requirement to reduce the risk of packaging contaminating products. Where companies are producing products for further processing, clear liners should not be used as they present a potential hazard for the next manufacturer. This clause does not apply to packaging used for sale to the final consumer. The company shall have a procedure to manage obsolete packaging (including labels). This shall include: 5.5.3 mechanisms to prevent accidental use of obsolete packaging control and disposal of obsolete packaging appropriate procedures for the disposal of obsolete printed materials (e.g. rendering trademarked materials unusable).

Interpretation

Obsolete packaging

Mis-labelling and mis-packing of product is a common cause of product recall. This is of particular concern when, for example, allergens are introduced which are not accurately reflected on the labelling. Effective management of packaging materials, particularly those that are printed, can minimise the risk of these incidents.

One of the key aspects of this management is the effective control of obsolete packaging (i.e. items that are no longer required) such as those that are out of date because of a change in the ingredients used in the product. At a minimum sites should have:

- mechanisms to prevent the accidental use of obsolete packaging (e.g. physical segregation in storage areas, clear 'do not use' labelling, blocks in electronic inventory systems)
- controls for the disposal of obsolete packaging (e.g. timescales for the disposal of materials; how accidental use will be prevented whilst waiting for disposal; and how materials will be disposed of)
- appropriate procedures for the disposal of obsolete printed materials (e.g. rendering trademarked materials such as out-of-date labels unusable).

5.6 PRODUCT INSPECTION AND LABORATORY TESTING

The company shall undertake or subcontract inspection and analyses which are critical to confirm product safety, legality, integrity and quality, using appropriate procedures, facilities and standards.

Interpretation

The company needs to identify and schedule the inspection and analyses which are critical for the products it produces. For example, critical analyses may include:

- known product safety risks associated with the product type or identified during the HACCP risk assessment
- legal requirements, particularly those associated with the country of intended sale (where this is known)
- product integrity (e.g. where a genuine risk of adulteration, substitution or fraud has been identified during the vulnerability assessment described in section 5.4)
- quality attributes (e.g. where these form part of a specification agreed with the customer).

The frequency and type of inspection and tests are not prescribed by the Standard as these should be risk-based and specific to the type of products (see clause 5.6.1.1).

5.6.1 PRODUCT INSPECTION AND TESTING

CLAUSE	REQUIREMENTS
5.6.1.1	There shall be a scheduled programme of product testing which may include microbiological, chemical, physical and organoleptic testing according to risk. The methods, frequency and specified limits shall be documented.
Interpretation	Product test schedules The company needs to have a documented schedule of tests which are carried out on the products. The objective of these tests is to ensure that products are manufactured to specification and in compliance with safety and legislative requirements. The HACCP study is likely to identify some of the tests required and their frequency. However, other tests which ensure the quality of the product and which may not have been included within the HACCP study must be considered. The frequency and type of product tests should be based on risk and on any particular customer requirements. The site is expected to be able to explain and justify the basis for the frequency of tests with reference to historical or scientific information as appropriate.
	The test method and specifications for each test must be documented. Where the results of a test are not quantitative (e.g. bake colour, texture or organoleptic tests), colour standards or reference samples must be used to provide a reference point for the test results (i.e. to define pass/fail criteria).
	Where tests are completed on site, the location of the testing should be considered; for example, laboratory facilities will need appropriate siting and controls (clause 5.6.2.2) and organoleptic tests should be completed in a designated area and not on the production line.
5.6.1.2	Test and inspection results shall be recorded and reviewed regularly to identify trends. The significance of external laboratory results shall be understood and acted upon accordingly. Appropriate actions shall be implemented promptly to address any unsatisfactory results or trends.
Interpretation	Reviewing test results Systems of recording and review must be formalised and must include evidence of actions taken on identified trends, or where unsatisfactory results have been recorded. The use of graphs or charts of test results provides a good method of identifying trends and anomalous results.
5.6.1.3	The site shall ensure that a system of validation and ongoing verification of the shelf life is in place. This shall be based on risk and shall include sensory analysis and, as applicable, microbiological testing and relevant chemical factors such as pH and $a_{\rm w}$. Records and results from shelf-life tests shall verify the shelf-life period indicated on the product.

CLAUSE **REQUIREMENTS**

Interpretation

Shelf-life verification

Sites are expected to have a programme of ongoing shelf-life validation and verification across their range of products or product types. To achieve this, samples should be retained from some or all production runs.

Records must be available supporting the declared shelf life for each product or group of similar products. These may include microbiological and sensory analyses, as well as relevant chemical factors such as pH and a... Shelf-life trials extending beyond the stated life of the product, to ensure a margin of safety, may be required for some product types.

Where products have long shelf lives (e.g. some canned products), the shelf life should be based on similar products and take into account any particular features of the new product. The justification for the shelf life must be documented.

5.6.2 LABORATORY TESTING

CLAUSE REQUIREMENTS Pathogen testing (including pathogens tested as part of the environmental testing) shall be subcontracted 5.6.2.1 to an external laboratory or, where conducted internally, the laboratory facility shall be fully segregated from the production and storage areas and have operating procedures to prevent any risk of product contamination. Interpretation Pathogen-testing facilities The requirements apply specifically to the testing of pathogens and not to general microbiological tests such as those for yeasts and moulds, total viable count (TVC) or coliforms (while these need to be carefully controlled, they present a lower level of risk). If pathogen-testing facilities are not carefully managed, they could present a risk to products. Pathogen testing also tends to be a specialised activity requiring specific facilities, and consequently it is usually outsourced to a specialist laboratory. Where pathogen testing is carried out on the production site, the test facility must be physically segregated from production and storage areas. The company must have documented procedures to prevent product contamination and must be able to justify the controls in place. Consideration of the design of the laboratory is covered in clause 5.6.2.2. Where routine testing laboratories are present on a manufacturing site, they shall be located, designed and 5.6.2.2 operated to eliminate potential risks to product safety. Controls shall be documented, implemented and include consideration of: design and operation of drainage and ventilation systems access and security of the facility movement of laboratory personnel protective clothing arrangements processes for obtaining product samples disposal of laboratory waste. Interpretation Design of laboratory facilities If a laboratory is present within the site, documented control procedures are required to eliminate potential

risks to product safety. These include:

- design of the facility (particularly the design and operation of drainage and ventilation systems)
- how personnel move around the facility
- control of access and security
- procedures which ensure that protective clothing arrangements are suitable (e.g. not wearing laboratory clothing in other areas of the site, especially in production and storage areas)
- procedures for obtaining product samples and disposal of waste.

Accreditation to ISO 17025 or a similar recognised national standard with equivalent requirements will demonstrate that the laboratory meets these requirements.

CLAUSE	REQUIREMENTS
5.6.2.3	Where the company undertakes or subcontracts analyses which are critical to product safety or legality, the laboratory or subcontractors shall have gained recognised laboratory accreditation or operate in accordance with the requirements and principles of ISO/IEC 17025. Documented justification shall be available where accredited methods are not undertaken.
Interpretation	Analyses critical to safety and legality This clause applies to tests which are critical to product safety or legality. Results from such tests must be credible and may be called upon in a court of law.
	The company needs to identify which tests are critical to product safety or legality, such as compliance with label claims/declarations (e.g. nutritional claims, alcohol content) and tests for contamination (e.g. by pesticides, aflatoxins).
	Note that while the laboratory itself may have accreditation, the actual test methods must also be accredited. Any method of analysis that is not accredited needs justification as to why it was used (e.g. it may be a method for which no accreditation is yet available). Where critical tests are carried out by non-accredited laboratories (either contracted or on-site laboratories), there must be suitable documentary assurances that the laboratory is working to the requirements and principles of ISO 17025. This must include confirmation of the laboratory's procedures to meet the following general principles:
	 staff competency and documented training documented test methodology based on accepted standards equipment that is fit for purpose and appropriately calibrated a documented quality assurance programme, including paired testing, ring testing etc. completion of internal audits of the laboratory's operation.
5.6.2.4	Procedures shall be in place to ensure reliability of laboratory results, other than those critical to safety and legality specified in clause 5.6.2.3. These shall include:
	 use of recognised test methods, where available documented testing procedures ensuring staff are suitably qualified and/or trained and competent to carry out the analysis required use of a system to verify the accuracy of test results (e.g. ring or proficiency testing) use of appropriately calibrated and maintained equipment.
Interpretation	Management of tests not critical to safety and legality This requirement applies to non-critical product testing. While such tests need not be carried out by a laboratory accredited to ISO 17025, it is nonetheless important that the results can be relied upon. The clause sets out the documented procedures which must be in place to provide confidence in reliability.
5.6.2.5	The significance of laboratory results shall be understood and acted upon accordingly.
	Appropriate action shall be taken promptly to address any unsatisfactory results or trends.
	Where legal limits apply, these shall be understood and appropriate action taken promptly to address any exceedance of these limits.
Interpretation	Laboratory test results Laboratory tests shall be selected to check for the presence of a specific adulterant (e.g. pesticides, heavy metals or microbiological contamination), test for conformity to a specification or claim (e.g. salt content), or monitor trends (e.g. environmental monitoring). Wherever testing is carried out, acceptable or action limits should be established so that the results of the tests can be interpreted. In some instances the interpretation of the results may be provided by the laboratory (e.g. multiscreen pesticide analysis or heavy metal testing). It is important that the person at the site receiving and reviewing the test results is able to interpret their significance and explain this to an auditor during the site audit.
	The review of laboratory results should be recorded, noting the name of the person undertaking the review and a record of any actions taken. Where test results are found to be out of specification, there should be clear protocols on the actions to be taken (e.g. product hold and retesting; notification of a customer; or possibly product recall depending on the significance of the test result).

5.7 PRODUCT RELEASE

The site shall ensure that finished product is not released unless all agreed procedures have been followed.

Interpretation

The site must have a process to ensure that finished product is not released from its control until all production checks have been completed and reviewed. Completion of end-product testing may not be applicable prior to the release of all products. (An example would be microbiological checks on short-shelf-life products such as sandwiches.) However, there must be appropriate checks on the CCPs to ensure that the process was within specification before product is released from the company's control. This allows product to be held where a review of the process checks identifies a potential problem.

CLAUSE	REQUIREMENTS
5.7.1	Where products require positive release, procedures shall be in place to ensure that release does not occur until all release criteria have been completed and the release has been authorised.
Interpretation	Management of positive release Where products are held either on or off site awaiting positive release, there need to be documented procedures describing the process for release and who authorises it. The procedures need to be sufficiently robust so that accidental release cannot occur; for example, having password control on a computerised system to prevent unauthorised picking of held product, or using the physical identification of pallets in the warehouse.

5.8 PET FOOD

The site shall ensure that pet food products are safe and fit for intended use.

Interpretation

Pet food is manufactured in the same type of environment as food for human consumption but there are some specific additional requirements that reflect the nature of pet food manufacture. Where sites do not manufacture pet food, this section can be marked as not applicable (n/a).

CLAUSE	REQUIREMENTS
5.8.1	The site shall ensure pet food is formulated/designed for the intended use (e.g. where products are designed for complete diet or as a complementary product).
Interpretation	Pet food product development Pet food is unique in that a product can be designed for complete diet (i.e. a pet may eat the same product at every meal, often without other additions to the diet) or as a complementary product (e.g. as an addition to certain meals or as an occasional treat). The formulation and design (e.g. nutritional composition, portion size etc.) is therefore likely to be different depending on the intended frequency of consumption (complete or complementary).
	Auditors will expect to see documented evidence that this formulation requirement has been considered (e.g. in new product development processes, recipe design and/or specifications).
5.8.2	Where a site's product range includes pet food products for different animal species, the site shall have specific procedures for the management of any ingredients, raw materials, products or rework that could be harmful to unintended recipients.

CLAUSE **REQUIREMENTS** Interpretation Pet foods for different species Sites that produce pet food for many different animal species (e.g. cats, dogs) must be aware that some ingredients cannot be safely eaten by all species without deleterious effect. For example, there are foods that can be fed to cats but not dogs because of their different dietary requirements. Therefore, sites should consider: a system to identify materials that could potentially be harmful to unintended recipients (i.e. to other species of pets). This shall include raw materials, processing aids, intermediate and finished products, and any new product development ingredients or products • a system to ensure incorrect ingredients cannot be used procedures (e.g. cleaning procedures) to prevent cross-contamination from the production of one particular pet food into the subsequent pet food for a different species • specific procedures to ensure correct labelling of intended animal species and any limitations on use. Where the site manufactures, processes or packs pet food products that contain medicinal substances, 5.8.3 the site shall have specific procedures for the management of the medicated raw materials and finished products. At a minimum, these procedures shall include: • identification of medication-containing materials handled on site. These can be raw materials, processing aids, intermediate and finished products, rework or any new product or product development ingredients mechanisms to ensure the correct concentrations of medicinal substances in finished products • procedures (e.g. cleaning procedures) to prevent contamination of non-medicated pet food with materials containing medicinal substances specific procedures to ensure the correct labelling of medicated pet food. Interpretation **Medicated products** Where a site manufactures pet food which contains medicinal substances, it is vital that these materials (both the raw materials and the finished products) are controlled to ensure correct doses and prevent cross-contamination. At a minimum, procedures must: ensure clear identification of medicated materials (raw materials, processing aids, intermediate products, rework and finished products) throughout the receipt, storage and manufacturing processes, so that all staff are aware that the material is medicated and the nature of the medication. This is important where multiple medicated substances are handled on site • include processes to evaluate the correct doses of medicated substances for new product development, recipes and specifications ensure that only the correct amounts of medicated substances are added to the batch during manufacture. Any features of the manufacturing process that could affect these concentrations (e.g. uneven distribution through the batch or a production process that effectively concentrates the medication such as a cooking process that causes water loss) must be considered prevent cross-contamination from the production of medicated pet food into subsequent pet food which should not contain the medication. This applies principally to cleaning procedures.

Sites should also be aware that medicated substances are often subject to regulatory requirements

(e.g. specific storage requirements or controlled disposal of waste).

6 PROCESS CONTROL

6.1 CONTROL OF OPERATIONS

FUNDAMENTAL

The site shall operate to procedures and/or work instructions that ensure the production of consistently safe and legal product with the desired quality characteristics, in full compliance with the HACCP food safety plan.

Interpretation

The principle of these requirements is to ensure that the documented HACCP or food safety plan is put into operation on a day-to-day basis, together with effective procedures to ensure that the product can be produced consistently to the specified quality.

CLAUSE	REQUIREMENTS
6.1.1	Documented process specifications and work instructions/procedures shall be available for the key processes in the production of products to ensure product safety, legality and quality. The specifications/procedures as appropriate shall include:
	 recipes – including identification of any allergens mixing instructions, speed, time equipment process settings cooking times and temperatures cooling times and temperatures labelling instructions coding and shelf-life marking any additional critical control points identified in the HACCP or food safety plan.
	Process specifications shall be in accordance with the agreed finished product specification.
Interpretation	Manufacturing instructions and process specifications Documented process specifications, procedures or work instructions must be available for all key stages of the operation. These documents must be readily available to staff in the area in which the activity is undertaken. The documents must be sufficient to ensure that all key process parameters are specified and controlled, thereby ensuring that manufactured product consistently meets safety, legality and quality specifications.
	Staff must be trained in the work instructions relevant to their role (section 7.1). Manufacturing instructions and process specifications must correctly reflect customer requirements, such as final product specifications. The equipment settings must be checked to ensure that the equipment is set up correctly for the specific product in production, and labelling instructions (such as particular requirements for label positioning on the pack) must be followed.
	Specifications for work in progress are not applicable to all products. For example, when a product is manufactured in several stages and combined to form the final product, or when a product is partially processed and retained for future processing, a separate specification for that product may be required. It must detail the important criteria that affect the finished product quality or safety parameters (e.g. brix, weight, colour, shelf life or storage conditions) and must include the acceptable range of each parameter.
	Simple photographic specifications, including minimum, target and maximum grading levels for parameters such as size and colour, may be appropriate for production staff.
6.1.2	Where equipment settings are critical to the safety or legality of the product, changes to the equipment settings shall only be completed by trained and authorised staff. Where applicable, controls shall be password-protected or otherwise restricted.
Interpretation	Equipment settings As with any electronically stored data or records, equipment settings for product safety or quality should be adjusted only by trained and competent members of staff, and controls should be in place to ensure that this remains the case.

CLAUSE	REQUIREMENTS
6.1.3	Process monitoring, such as of temperature, time, pressure and chemical properties, shall be implemented, adequately controlled and recorded to ensure that product is produced within the required process specification.
Interpretation	Process monitoring Processes must be adequately controlled and monitored to ensure that product is produced within specification. These processes may include CCPs or prerequisite programmes addressing issues such as temperature, time, pressure and chemical properties.
	Monitoring must be carried out at suitable frequencies based on experience of the reliability of equipment, frequency of process changes, and risk to product safety and quality. The frequency of checks should be included on recording forms and/or in procedure documentation. A record of all monitoring must be maintained.
	Where processes are shown to have exceeded defined limits, corrective actions must be taken and this action must be recorded (clause 6.1.6).
6.1.4	In circumstances where process parameters or product quality are controlled by in-line monitoring devices, these shall be linked to a suitable failure alert system that is routinely tested.
Interpretation	In-line monitoring devices Where process parameters or product quality are controlled by in-line monitoring devices (e.g. automatic temperature or pH loggers), they must be linked to a suitable failure alert system (e.g. audible/visual alarm, machine stop function or product divert system) which is activated when defined parameters are exceeded. This alarm must be tested routinely to ensure that it functions properly, and records must be maintained.
6.1.5	Where variation in processing conditions may occur within equipment critical to the safety or quality of products, the processing characteristics shall be validated and verified at a frequency based on risk and performance of equipment (e.g. heat distribution in retorts, ovens and processing vessels; temperature distribution in freezers and cold stores).
Interpretation	Critical safety or quality parameters The objective is to ensure that products can be consistently produced and stored within clearly defined parameters (e.g. within defined temperatures). It is recognised that process conditions are often not uniform throughout a chill store or an oven. It is important, therefore, to identify hot or cold spots, both to try to improve uniformity and to identify worst-case scenarios to ensure that all products meet at least the minimum process conditions.
	For example, the Standard expects heat-distribution studies to be carried out on cooking equipment wherever small variations in process temperature may affect the safety of the products. Heat-distribution studies of a static oven may identify cold spots. If it is not possible to make adjustments to eliminate these cold spots, the areas should be used as the worst-case scenarios when completing heat-distribution studies.
	When assessing whether to undertake temperature-distribution studies on chill or freezer facilities, the level of risk will depend on the product, the time spent in store and any margin allowed by the temperature settings (e.g. setting the temperature at -20° C to ensure achievement of -18° C). Temperature-distribution studies would not normally be necessary for small chill or cold stores where product is stored only for short periods.
	When testing equipment, any seasonal variations in performance must be considered, especially when trying to assess worst-case scenarios. For example, a chiller evaluated in winter may not give the same results in summer, especially if there are large seasonal differences in the ambient temperatures. Some refrigeration equipment may be at the limit of their performance on especially hot days if temperature parameters have not been properly specified.
6.1.6	In the case of equipment failure or deviation of the process from specification, procedures shall be in place to establish the safety status and quality of the product to determine the action to be taken.

CLAUSE

REQUIREMENTS

Interpretation

Equipment failure and results outside defined limits

In cases of equipment failure or deviation from process or specification (e.g. outside the critical limit), the company must have defined procedures in place to ensure that the product is safe prior to its release. At a minimum, this should include:

- identification of all products at risk (i.e. product produced since the last satisfactory check)
- how the affected product will be assessed for suitability/safety (this may include sensory testing, microbiological sampling, reference to thermal process data or the use of mathematical modelling techniques, depending on the product and issue)
- who is authorised to undertake action and make a final decision on the affected product.

Records must be kept of this deviation and the action taken.

6.2 LABELLING AND PACK CONTROL

FUNDAMENTAL

The management controls of product labelling activities shall ensure that products will be correctly labelled and coded.

Interpretation

One of the common causes of withdrawals and recalls is incorrectly packed products and labelling (e.g. allergen labelling) that does not reflect the actual content of the product. Therefore the aim of this section is to ensure that the site has effective procedures to manage packing operations and to pack products in the correct packaging.

CLAUSE	REQUIREMENTS
6.2.1	There shall be a formal process for the allocation of packaging materials to packing lines and control in the packing area which ensures that only the packaging for immediate use is available to the packing machines.
	Where offline coding or printing of packaging materials occurs:
	 setting and amendments to the printer parameters (e.g. the input of, or changes to, date codes) shall only be completed by an authorised member of staff controls shall be in place to ensure that only correctly printed material is available at the packing machines.

Interpretation

Allocation of packaging materials

Packaging for each production run must be brought to the line in a formal and controlled manner following a documented process.

The integrity of date codes is vital to ensure product safety is maintained. Where date codes (or other information) are applied to packaging or product on site, this must be controlled so that only authorised (and competent) personnel can set or make the changes to printers (e.g. inputting the required date code).

Only the packaging required for immediate use should be available to the packing line at any one time. Ideally, this will be achieved by only releasing new packaging from the store when all packaging from the previous run has been removed from the area. Where this is not possible (e.g. because of off-site packaging stores), a mechanism must be in place to ensure that only the relevant packaging can be released to the packing line (e.g. by storing packaging in a designated, secure location with authorised access).

Where multiple component packaging is used (e.g. pots with separate lids, multi-packs or packaging with separate labels), then the controls will need to apply to all the individual parts, to ensure they all match the product being produced.

6.2.2

Documented checks of the production line shall be carried out before commencing production and following changes of product. These shall ensure that lines have been suitably cleared and are ready for production. Documented checks shall be carried out at product changes to ensure that all products and packaging from the previous production have been removed from the line before changing to the next production.

CLAUSE REQUIREMENTS

Interpretation

Production line checks

Documented checks carried out on the production line before production commences will ensure that systems are correctly set and running. Checks must include confirmation that:

- lines have been suitably cleaned
- lines have been cleared of any packaging from previous production runs
- lines are ready for production, with CCPs and quality parameters correctly set (e.g. metal detector checks completed satisfactorily, cookers set to the correct temperature programme, correct packaging selected).

If the line is set up with equipment that has not been used for some time, then there may be a need to re-disinfect food contact surfaces immediately prior to use.

Checks are also required following changes of product to ensure that all product and packaging from the previous production has been removed and, where appropriate, to ensure that cleaning has been completed correctly and the line is correctly set up for the new product. Line checks are usually the responsibility of the line manager or supervisor. Evidence that checks have been carried out (e.g. line check sheets) and guidelines on the checks to complete should be available.

6.2.3

Procedures shall be in place to ensure that all products are packed into the correct packaging and correctly labelled. These shall include checks:

- at the start of packing
- during the packing run
- when changing batches of packaging materials
- at the end of each production run.

The checks shall also include verification of any printing carried out at the packing stage including, as appropriate:

- date coding
- batch coding
- quantity indication
- pricing information
- bar coding
- country of origin
- allergen information.

Interpretation

Packaging controls

A high proportion of product withdrawals/recalls are because of products being packed into incorrect packaging or incorrectly labelled. Therefore, specific documented packaging controls must be in place. Particular care is required where:

- a number of similar-looking products are manufactured
- a standard product may be packed into different types of packaging
- there is a family of very similar labels for a product range, each containing different information (e.g., the presence of different allergens or different use-by/best-before dates).

Procedures must be in place to verify that adequate checks have been carried out to minimise potential errors. The frequency of checks must be predefined, based on risk assessment, but at a minimum must include those checks as specified in the requirement. The packing run can be defined as a batch or lot, or another distinct period. The intention is to ensure that the site is maintaining control over pre-printed packaging materials and their packing.

The procedures must also include verification of any code information or other printing carried out at the packing stage (i.e. applied by the site). This verification shall include those checks as specified in the requirement.

CLAUSE REQUIREMENTS Where online verification equipment (e.g. bar code scanners) is used to check product labels and printing, 6.2.4 the site shall establish and implement procedures for the operation and testing of the equipment to ensure that the system is correctly set up and capable of alerting or rejecting product when packaging information is out of specification. At a minimum, testing of the equipment shall be completed at: • the start of the packing run • the end of the packing run a frequency based on the site's ability to identify, hold and prevent the release of any implicated materials should the equipment fail (e.g. during the packing run or when changing batches of packaging materials). The site shall establish and implement procedures in the event of a failure in the online verification equipment (e.g. a documented and trained manual checking procedure). Interpretation Online vision equipment Some sites have found that the use of automated online vision equipment (e.g. bar code scanners or cameras) provides a beneficial check of the accuracy of the packing operation. This equipment is able to check that the correct packaging has been consistently used throughout the packing run and that the correct date code has been applied. Any out-of-specification information (such as when the wrong packaging is used) is identified by this equipment, and staff are either alerted or the product is rejected out of the product flow. Where a company chooses to use this type of equipment, it is important that procedures are in place to ensure that it is correctly set up and operates effectively throughout the packing run. At a minimum this will include checks: at the beginning of the packing run, so that the equipment is confirmed to be set up correctly before

at the end of the packing run, to confirm that the equipment is still operating effectively when packing

• during the packing run, at a frequency based on risk (i.e. based on the site's ability to take appropriate action in the event of an adverse test result, before the implicated materials are released from the site).

alternating packs of both correct and incorrect packaging). Depending on the function of the vision system, incorrect packaging might include the wrong packaging, an incorrect date code or an obscured label. It is important that these test packs are clearly marked so that they cannot inadvertently enter the process flow. The site must consider the procedures it would follow in the event of an equipment failure (e.g. a back-up plan).

Good practice is to test the online vision system prior to commencing the packing run (e.g. by using

packing commences

is completed

6.3 QUANTITY - WEIGHT, VOLUME AND NUMBER CONTROL

The site shall operate a quantity control system which conforms to legal requirements in the country where the product is sold and any additional industry sector codes or specified customer requirements.

Interpretation

The site must ensure that products meet the requirements of customers and the legislation of the country, state or territory where the product is sold.

CLAUSE	REQUIREMENTS
6.3.1	The frequency and methodology of quantity checking shall meet the requirements of the appropriate legislation governing quantity verification, and records of checks shall be retained.
Interpretation	Quantity control – legislative requirements The type of quantity control used (e.g. average weights, catch weight, minimum weight or count) may be determined by the company in conjunction with the requirements of the customer.
	The system used must operate to the legal requirements in the country, state or territory in which the product is sold.
	Adequate records must be kept or, where automatic check-weighing equipment is used, this must be properly set up and the rejection system tested according to industry-sector guidelines. Checks of automatic reject systems must be carried out using representative packs of the product being produced.
	Potential changes during transport and shelf life (e.g. weight loss during transport or water loss (desiccation) during storage) should be factored in, so that the weight at the end of shelf life continues to meet statutory and customer requirements.
6.3.2	Where the quantity of the product is not governed by legislative requirements (e.g. bulk quantity), the product must conform to customer requirements and records shall be maintained.
Interpretation	Quantity control – customer requirements Where there are no legislative requirements (e.g. where bulk quantities are supplied to the customer), procedures must be in place to ensure that customer requirements are met (e.g. monitoring by flow meter or calibrated weighbridge for tanker loads).
	Records must be maintained.
6.3.3	Where used, the site shall establish procedures for the operation and testing of online check weighers. At a minimum, this shall include:
	 consideration of any legal requirements responsibilities for testing the equipment operating effectiveness and any variations for particular products methods and frequency of testing the check weighers records of the test results.
Interpretation	Online check weighers The effective operation of a check weigher must be verified within the context of legal requirements (e.g. minimum fill weights against declaration), and their function must be assured through testing and operation.
	Methodology of testing should be documented and the expected output understood by the operator or person with responsibility for the check weigher.

6.4 CALIBRATION AND CONTROL OF MEASURING AND MONITORING DEVICES

The site shall be able to demonstrate that measuring equipment is sufficiently accurate and reliable to provide confidence in measurement results.

Interpretation

The site must ensure that key pieces of equipment that control and monitor processes are themselves confirmed as operating effectively and accurately. This is routinely confirmed by measurement against recognised standards. Where national or international standards do not exist, the company needs to demonstrate how the equipment is adequately monitored.

CLAUSE	REQUIREMENTS
6.4.1	The site shall identify and control measuring equipment used to monitor critical control points and product safety, legality and quality. This shall include, at a minimum:
	 a documented list of equipment and its location an identification code and calibration due date prevention from adjustment by unauthorised staff protection from damage, deterioration or misuse.
Interpretation	Identification and control of measuring equipment The site needs to identify the measuring equipment (e.g. scales, thermometers and pH meters) that is used to monitor CCPs, product safety, legality and quality. At a minimum, this equipment must be:
	 documented in a list which details the location of each item of equipment marked in accordance with its calibration requirements (e.g. an identification code and the calibration due date). This may be achieved by engraving the piece of equipment with a number that is cross-referenced to the documented list, or labelling the equipment with its calibration due date protected against unauthorised adjustment (e.g. through the use of programme ID codes or locking keys) protected from damage or misuse through good design or the training of staff.
6.4.2	All identified measuring devices, including new equipment, shall be checked and, where necessary, adjusted:
	 at a predetermined frequency, based on risk assessment to a defined method traceable to a recognised national or international standard where possible.
	Results shall be documented. Equipment shall be readable and be of a suitable accuracy for the measurements it is required to perform.
Interpretation	Calibration checks The site needs to establish the method by which the precision and accuracy of equipment is verified. This must include:
	 a predefined check frequency, based on a risk assessment (e.g. historical reliability, nature of use, manufacturer's recommendations) who is authorised to complete the checks (e.g. trained staff) the method to be used (which must, where possible, be traceable to a recognised standard, e.g. use of a master calibration thermometer that has a certified test certificate traceable to a national standard).
	Equipment must be of a suitable accuracy for the measurements it is required to perform. For example, where temperature is critical to the safety of a product (as in pasteurisation or the canning process), the measuring thermometer requires an accuracy of ± 0.5 °C, whereas a thermometer used to check vehicle temperatures may only need an accuracy of ± 1 °C.
6.4.3	Reference measuring equipment shall be calibrated and traceable to a recognised national or international standard and records maintained. The uncertainty of calibration shall be considered when equipment is used to assess critical limits.

CLAUSE	REQUIREMENTS
Interpretation	Reference equipment All reference equipment (e.g. a master thermometer) must be calibrated and traceable to a national or international standard.
	Where equipment is used to measure or monitor a critical limit, it is important that the tolerance (or uncertainty) of the calibration is considered. For example, if a thermometer is required to measure a critical limit of 72° C, but the calibration shows an uncertainty of 0.5° C, then it must be noted that a thermometer reading of exactly 72° C could in fact represent a true temperature of anywhere between 71.5 and 72.5° C (i.e. the temperature could be lower or higher than the critical limit). In this situation, to guarantee a minimum temperature of 72° C, it would be necessary for the reading on the thermometer to always be 72.5° C or higher.
	Records must be kept.
6.4.4	Procedures shall be in place to record actions to be taken when the prescribed measuring devices are found not to be operating within specified limits. Where the safety or legality of products is based on equipment found to be inaccurate, action shall be taken to ensure at-risk product is not offered for sale.
Interpretation	Equipment outside specified limits Documented procedures must detail the action to be taken when equipment is found to be outside specified limits. The documentation must specify what will be done and by whom, and must include what will happen to products that have been monitored by this equipment since the last successful check (to prevent at-risk products from being offered for sale).
	Records must be kept of the actions taken.

7 PERSONNEL

7.1 TRAINING: RAW MATERIAL HANDLING, PREPARATION, PROCESSING, PACKING AND STORAGE AREAS

FUNDAMENTAL

The company shall ensure that all personnel performing work that affects product safety, legality and quality are demonstrably competent to carry out their activity, through training, work experience or qualification.

Interpretation

Staff must be fully trained and competent to undertake their role. This will include all relevant staff whose roles affect product safety, legality and quality.

Seasonal/temporary personnel and contractors must be included. Where employment agencies are used for the provision of staff, all the requirements in this section need to be adequately met and evidenced. This may include: specifying company policies within any supply contract; obtaining evidence of staff training records from the agency prior to a staff member commencing work; and using a risk-based system to challenge staff understanding and ensure competence in carrying out roles.

Employment agencies are subcontracted service providers whose business is to assist companies in filling vacant positions. Agency staff are often used to fill temporary positions, such as those caused by seasonal variations in production.

CLAUSE	REQUIREMENTS
7.1.1	All relevant personnel, including agency-supplied staff, temporary staff and contractors, shall be appropriately trained prior to commencing work and adequately supervised throughout the working period.
Interpretation	Initial training and supervision The company must ensure that all staff, including temporary staff, agency-supplied staff (see statement of intent) and contractors, receive training to a level commensurate with their responsibility and the type of work they carry out. The following training options may be considered:
	 induction training for all staff, covering company policies on hygiene, allergens, quality requirements, entry and exit procedures, pest control, a basic introduction to HACCP etc. obtaining a qualification in 'basic food hygiene' for food handlers training in areas that impact food safety, such as cleaning, machine operation, quality inspections and sampling.
	All personnel must be adequately supervised throughout the working period. Particular attention should be paid to identifying the needs of temporary/seasonal workers and contractors. Good practice is for new starters to have additional supervision for a defined period. This additional supervision can be reduced or removed at the end of the period following a review of the employee's competency to complete the role (clause 7.1.7).
7.1.2	Where personnel are engaged in activities relating to critical control points, relevant training and competency assessment shall be in place.
Interpretation	Critical control point training To ensure that activities identified as CCPs within the HACCP or food safety plan are managed correctly, personnel involved in these areas must be appropriately trained in the procedure. This includes the operation of the control and monitoring activities and the implementation of corrective action. Clear, documented instructions must be available, detailing:
	 how to carry out the tasks when the task is to be completed records to be maintained action to be taken in the event of a non-conforming result.
	A competency assessment must take place on completion of the training and at predefined intervals (e.g. during internal audits of CCPs). The assessment needs to confirm that the procedure is being followed correctly, test knowledge of the corrective actions, and check for the completion of any relevant training.

CLAUSE	REQUIREMENTS
7.1.3	The site shall put in place documented programmes covering the training needs of relevant personnel. These shall include, at a minimum:
	 identifying the necessary competencies for specific roles providing training or other action to ensure staff have the necessary competencies reviewing the effectiveness of training delivery of training in the appropriate language of trainees.
Interpretation	Documented training programme The site must have a documented training programme showing what job role competencies are required; the actions taken to ensure that staff obtain these competencies; and a review of the effectiveness of these actions. For example, a job training matrix could list all of the site roles, with details of which procedures and work instructions are required for each role.
	Training must be delivered in an appropriate language for the trainee (e.g. by providing either written or oral translation where it is required). It is not a requirement for all documentation to be translated into every language of the workforce, but all staff must be able to understand the instructions necessary for their job. For example, hygiene rules may be provided in written translations or in pictorial format, while CCP monitoring instructions may be translated into the languages spoken by the staff involved in these areas.
	Training may be delivered internally or externally, but the company needs to ensure that the training has been effective. This can be achieved through assessment of the staff's ability to undertake the tasks they need to perform, by testing their knowledge, or by on-the-job assessment.
7.1.4	All relevant personnel, including engineers, agency-supplied staff, temporary staff and contractors, shall have received general allergen awareness training and be trained in the site's allergen-handling procedures.
Interpretation	Allergen training All personnel (including all agency-supplied and temporary staff, and contractors) involved in handling ingredients, equipment, utensils, packaging and products must have received training to raise awareness of food allergens and the specific allergen measures used by the company.
	The level of training should be appropriate to the individual's role. For example, junior staff may require only a general understanding of the importance of allergens (information that could be included as part of the induction process), plus any specific procedures in which they are involved. However, the technical team will require a more in-depth knowledge.
	Training records must be kept.
7.1.5	All relevant personnel (including relevant agency-supplied staff, temporary staff and contractors) shall have received training on the site's labelling and packing processes which are designed to ensure the correct labelling and packing of products.
Interpretation	Packing and labelling training Mis-packed and mis-labelled goods are the leading cause of product recalls across the world.
	This clause requires any personnel linked to the packing or labelling of raw materials, intermediates or finished product to be trained in, and kept up to date with, proper procedures. It is also useful for these staff to understand the implications of mis-packed or mis-labelled product.
7.1.6	Records of all training shall be available. These shall include, at a minimum:
	 the name of the trainee and confirmation of attendance the date and duration of the training the title or course contents, as appropriate the training provider for internal courses, a reference to the material, work instruction or procedure that is used in the training.
	Where training is undertaken by agencies on behalf of the company, records of the training shall be available.

CLAUSE	REQUIREMENTS
Interpretation	Training records Evidence of all training needs to be kept and must include all the details as listed in the requirement.
	These details may be included in the certificate of attendance provided at an external or internal course, or the course contents may be included in a personnel induction booklet that is cross-referenced with a record of the training completed (with trainee name, date and name of trainer, together with the name of any translator).
	Where training is internal, the site should retain reference to the material used (e.g. to the company procedure and its version number). Where the site has used 'on-the-job' or informal training methods (e.g. toolbox talks), a summary of the content could be used and made available for reference.
	Training records for any temporary staff, agency-supplied labour or external consultants must also be available.
7.1.7	The company shall routinely review the competencies of its staff. As appropriate, it shall provide relevant training. This may be in the form of training, refresher training, coaching, mentoring or on-the-job experience.
Interpretation	Competency review The company must ensure there is ongoing assessment of staff competencies in their roles (e.g. through one-to-one appraisals, team performance monitoring by line managers, review of the results of internal audits, or review of records).
	Where the need is identified (e.g. when a job role changes; following performance issues; or when there are changes in operating procedures such as a change in the requirements for a CCP), there must be appropriate refresher training (supplied internally or externally), coaching, mentoring or on-the-job experience to improve skills and understanding.

7.2 PERSONAL HYGIENE: RAW MATERIAL HANDLING, PREPARATION, PROCESSING, PACKING AND STORAGE AREAS

The site's personal hygiene standards shall be developed to minimise the risk of product contamination from personnel, be appropriate to the products produced and be adopted by all personnel, including agency-supplied staff, contractors and visitors to the production facility.

Interpretation

The site must have documented personal hygiene rules designed to prevent product contamination from personnel. These should be based on risk and may take into account different requirements for different product risk zones.

All personnel entering production areas (including raw material storage, processing, packing and storage areas) must adhere to the company's documented personal hygiene rules.

CLAUS	E	REQUIREMENTS
7.2.1		The requirements for personal hygiene shall be documented and communicated to all personnel. These shall include, at a minimum, the following:
		 watches shall not be worn jewellery shall not be worn, with the exception of a plain wedding ring, wedding wristband or medical alert jewellery rings and studs in exposed parts of the body, such as ears, noses and eyebrows, shall not be worn fingernails shall be kept short, clean and unvarnished false fingernails and nail art shall not be permitted excessive perfume or aftershave shall not be worn.
		Compliance with the requirements shall be checked routinely.

CLAUSE REQUIREMENTS

Interpretation

Documented personal hygiene policy

The site must document its personal hygiene requirements. At a minimum, these shall include:

- watches are not permitted in open product areas
- jewellery must not be worn apart from plain wedding rings or wristbands (i.e. without stones that may fall out). Exceptions must be minimal and must not constitute a risk to product (e.g. wrist bands identifying a particular medical condition, such as epilepsy or an allergy, may be worn where product is not at risk of contamination). Where religious reasons prevent the removal of an item of jewellery, then it must be covered and the site must complete a risk assessment to confirm how this will be achieved (e.g. by totally covering the item with the wearer's clothing, or by wearing overalls that are buttoned up to cover the item)
- the potential for broken, damaged or lost glasses and contact lenses to become a foreign-body risk should be considered
- rings and studs in exposed parts of the body such as ears, noses and eyebrows must not be worn
- long fingernails are a contamination hazard since they may break off, and hence are not permitted; nor are
 nail varnish, nail art or false nails. Fingernails must be kept clean, commensurate with the level of hygiene
 expected within a food manufacturing environment. Where visitors cannot comply with these rules, other
 controls (such as limiting where visitors may enter and what they may touch, and the obligatory use of
 gloves) must be implemented to minimise the risk of contamination
- excessive perfume or aftershave must not be worn as this has the potential to taint foods.

These requirements are applicable to raw material handling, preparation, processing, packing and storage areas. The requirements for staff working solely in enclosed product areas may be relaxed where no risk is presented to the products.

The requirements must be communicated to all personnel (e.g. through induction training and sign-in procedures for visitors and contractors). Consideration must be given to staff who are not native speakers and appropriate methods of training (e.g. use of translators) must be provided for them.

Compliance with requirements must be checked regularly, for example by incorporating checks into daily or weekly good manufacturing practice audits, or through the questioning of personnel at regular intervals.

7.2.2

Hand-washing shall be performed on entry to the production areas and at a frequency that is appropriate to minimise the risk of product contamination.

Interpretation

Hand-cleaning

Hand-cleaning must be conducted at a frequency appropriate to the level of risk to the product being produced and in line with good industry practice. At a minimum, hands must be washed before staff enter the production area and whenever an activity is undertaken that could potentially be a risk to products (e.g. after going to the toilet, eating, smoking, blowing noses, sneezing or handling shoes).

Appropriate instructions for hand-washing, considering the language needs of staff (e.g. including pictorial instructions), must be provided (clause 4.8.4).

Further guidance

Introduction to hand-washing techniques

Hand-washing is recognised as an effective way to reduce the risk of contaminating food with microorganisms such as *E. coli*, *Salmonella* and *Staphylococcus aureus*. However, a number of studies have shown that people either do not wash their hands or fail to clean them effectively. So it is vital that food companies not only provide staff with appropriate facilities to wash their hands but also ensure staff are aware of the correct procedure to follow.

What makes a good hand-washing procedure?

Frequency

Hand-cleaning should be carried out as often as is appropriate to the level of risk to the product. At a minimum hands should be washed:

- before entering production areas
- after any break which involves leaving the production area
- after going to the toilet
- after eating or smoking
- after blowing your nose.

See also clause 8.4.1 for hand-washing facilities and procedures in high-risk and high-care zones.

159

CLAUSE

REQUIREMENTS

Method

There are a number of steps in an effective hand-washing procedure:

- wet hands with water
- apply soap
- rub the hands so that all the parts of the hands are cleaned, including palms, backs of hands, between fingers, backs of fingers, thumbs and fingertips
- rinse hands to remove soap
- dry hands thoroughly, as careful drying is a vital step in preventing the contamination of food products.

For a pictorial example of hand-washing, visit http://www.who.int/gpsc/5may/resources/posters/en/

In addition to the above routine, good practice is to apply a sanitiser such as an anti-bacterial hand gel after the hands have been washed and dried. An effective hand-washing routine should take approximately 40–60 seconds to complete.

Training

It is important that a good hygiene culture operates within the site so that an effective hand-washing routine becomes normal, everyday behaviour. This means that all new staff should be trained (e.g. during induction training) in the site's hand-cleaning procedures and understand the importance of them. Regular updates can help ensure the information remains fresh in people's minds.

Facilities

For a description of hand-washing facilities, see the guidance for clause 4.8.4.

Hand-washing process

For current best practice, please refer to http://www.who.int/gpsc/5may/resources/posters/en/

Quick tips

- Ensure staff understand the importance of hand-washing.
- Ensure staff are trained in the procedure of hand-washing.
- Provide sufficient and adequate facilities.

7.2.3

All cuts and grazes on exposed skin shall be covered by an appropriately coloured plaster that is different from the product colour (preferably blue) and contains a metal detectable strip. These shall be site-issued and monitored. Where appropriate, in addition to the plaster, a glove shall be worn.

Interpretation

Cuts and grazes

Cuts and grazes on exposed areas of skin must be covered to prevent contamination of product. To minimise the potential for plasters or band-aids to contaminate product, they must be controlled by the site (e.g. through the use of an issue procedure, where numbered plasters or band-aids are documented in a log, stating when and to whom they were issued). The site may consider the need for an audit of plasters at the end of the shift and for staff to immediately inform supervisors of any loss.

Plasters or band-aids must be visually distinct (preferably blue) and include a metal-detectable strip. This applies even where the site does not use metal detectors, as many products are sold for further processing and the plaster or band-aid could therefore be detected at a later stage in the supply chain. Where appropriate, in addition to the plaster or band-aid, a glove must be worn.

7.2.4

Where metal detection equipment is used, a sample from each batch of plasters shall be successfully tested through the equipment and records shall be kept.

Interpretation

Metal-detectable plasters

To ensure that each batch of plasters purchased fulfils the metal-detectable requirement, a sample from each batch must be tested to confirm that it is successfully rejected by the metal detector in use. Records must be kept.

Where the site does not use metal detectors, this requirement (for keeping a sample of the batch of plasters) will not apply.

7.2.5

Processes and written instructions for staff shall be in place to control the use and storage of personal medicines, so as to minimise the risk of product contamination.

Interpretation Personal medicines Personal medicines need to be controlled to ensure they do not constitute a risk to product. The site must have a documented procedure on the control and storage of medicines. Wherever possible, medicines should not be taken into production areas (e.g. they could be stored in lockers along with other personal items). However, where staff have a medical need to keep personal medicines with them (e.g. they have asthma or diabetes), procedures must be in place to control these medicines (such as a requirement to notify the company of the defined medical need). Consideration should be given to the format and packaging of the medicines (e.g. glass bottles) to minimise the potential risk of product contamination.

7.3 MEDICAL SCREENING

The company shall have procedures in place to ensure that employees, agency staff, contractors or visitors are not a source of transmission of food-borne diseases to products.

Interpretation

To ensure that all persons who will come into contact with food production and storage areas are not the source of a hazard, the company must have procedures in place by which staff and visitors are fully informed of the health conditions which prevent them from working in food production and storage areas.

CLAUSE	REQUIREMENTS
7.3.1	The site shall make employees aware of the symptoms of infection, disease or condition which would prevent a person working with open food. The site shall have a procedure which enables notification by employees, including temporary employees, of any relevant symptoms, infection, disease or condition with which they may have been in contact or be suffering from.
Interpretation	Illness notification procedures for employees Personnel need to receive, as part of their training, clear instructions on the potential risks of foodborne disease and the site's procedures for illness notification. Employees who are suffering from symptoms which may place products at risk must be prevented from working with open food.
	The site must be expected to define the symptoms or infections of concern, as advised by local legislation (e.g. a list of communicable diseases). These policies must be documented.
	This requirement covers all employees (including temporary staff and those employed via an employment agency). The site may consider the use of a pre-employment and/or return-to-work medical questionnaire or medical examination (e.g. stool testing), as appropriate to the risk.
	The use of suitably trained and competent persons and external medical experts may be required, particularly where privacy laws exist.
7.3.2	Where there may be a risk to product safety, visitors and contractors shall be made aware of the types of symptoms, infection, disease or condition which would prevent a person visiting areas with open food. Where permitted by law, visitors shall be required to complete a health questionnaire or otherwise confirm that they are not suffering from any symptoms which may put product safety at risk, prior to entering the raw material, preparation, processing, packing and storage areas.
Interpretation	Illness notification procedures for visitors to the site The site must ensure that visitors and contractors who enter areas where there may be a risk to product safety, or who undertake work that may constitute a risk to product, are informed of the site's policies and the medical conditions (e.g. the symptoms) that would prevent entry into production, storage or open product areas.
	Where permitted by legislation, visitors must be screened by use of a health questionnaire. The site must ensure that regular visitors and contractors, such as external company staff or pest control providers, are included. Where questionnaires are used, these must be reviewed by a competent person.
	The procedure must be documented.

CLAUSE	REQUIREMENTS
7.3.3	There shall be procedures for employees, contractors and visitors relating to action to be taken where they may be suffering from or have been in contact with an infectious disease. Expert medical advice shall be sought where required.
Interpretation	Documented infectious disease procedure Where staff, visitors or contractors declare they are suffering from, or have been in contact with, the identified diseases, infections etc., they must be subject to, and informed of, the procedures to prevent product contamination. This will usually include relocation to a role where they are not in contact with open products.

7.4 PROTECTIVE CLOTHING: EMPLOYEES OR VISITORS TO PRODUCTION AREAS

Suitable site-issued protective clothing shall be worn by employees, contractors or visitors working in or entering production areas.

Interpretation

Protective clothing includes uniforms, overalls, head coverings (such as hats and hairnets), shoes and boots, aprons and gloves (whether disposable or washable). A suitable design of protective clothing must be provided to all employees, visitors and contractors working in or visiting production areas.

CLAUSE	REQUIREMENTS
7.4.1	The company shall document and communicate to all employees (including agency and temporary personnel), contractors or visitors the rules regarding the wearing of protective clothing in specified work areas (e.g. production areas, storage areas etc.). This shall also include policies relating to the wearing of protective clothing away from the production environment (e.g. removal before entering toilets, and use of canteen and smoking areas).
Interpretation	Documented protective clothing policy The company is required to determine the procedures for application and use of protective clothing based on a risk assessment. The risk assessment must consider foreign-body, microbiological and allergen risks as appropriate, as well as general good-practice principles. It must document:
	 what must be worn (e.g. footwear, overalls and hair covering) and the design of each where clothing must be put on and taken off, including designated area(s) for changing the order in which clothing is applied (e.g. hairnet, footwear, wash hands and then overall or coat) where protective clothing will be stored when not in use special requirements for specific areas removal of protective clothing before entering toilets procedures for the removal of protective clothes in canteens and smoking areas areas where the product is fully enclosed and has no or very little risk of contamination from the factory environment during normal production.
	The requirement to wear full company-issued protective clothing would not be absolute where:
	 all products are fully enclosed the product would, if it were not fully enclosed, be classed as a low-risk product the area is separate from areas containing open product staff do not need to pass through open product areas to access the area.
	The wearing of a company uniform is preferred. Where personal clothing is allowed, sites must provide guidance on the standards of clothing which are acceptable.
	Wherever product lines are entered (e.g. adjustments at the filler), protective clothing and hair coverings must be worn.

CLAUSE	REQUIREMENTS
	Protective clothing shall be available that:
7.4.2	 is provided in sufficient numbers for each employee is of suitable design to prevent contamination of the product (at a minimum containing no external pockets above the waist or sewn-on buttons) fully contains all scalp hair to prevent product contamination includes snoods for beards and moustaches, where required, to prevent product contamination.
Interpretation	Availability and design of protective clothing Clothing must be available for all staff working in production and storage areas (including employment agency staff, contractors etc.). Items must be provided in sufficient numbers so that they may be maintained in an acceptable condition during working (e.g. to allow for washing).
	The company needs to consider the design of protective clothing and ensure that it is suitable for the production processes. At a minimum:
	 the clothing must not include external pockets above the waist (e.g. no pockets in coats) and must not have sewn-on buttons the company must consider the design of protective footwear for production areas and must provide footwear that can be kept clean headwear such as mob hats or hairnets must ensure that head hair is completely covered to minimise potential contamination snoods must be provided for staff or visitors who have beards or moustaches, where protection is needed to prevent product contamination. Clear rules must be in place and understood by staff, based on an assessment by the company.
7.4.3	Laundering of protective clothing shall take place by an approved contracted or in-house laundry using defined criteria to validate the effectiveness of the laundering process. The laundry must operate procedures which ensure:
	 adequate segregation between dirty and cleaned clothes effective cleaning of the protective clothing cleaned clothes are supplied protected from contamination until use (e.g. by the use of covers or bags).
	Washing of protective clothing by the employee is exceptional but shall be acceptable where the protective clothing is to protect the employee from the products handled and the clothing is worn in enclosed product or low-risk areas only.
Interpretation	Laundry

Interpretation Laundry

Protective clothing may be cleaned by contracting the services of a specialised laundry, by laundering in-house or, in exceptional circumstances, by employees laundering their own clothes.

External contracted services must be incorporated within the company's purchasing supplier approval programme (clause 3.5.3.1) and have systems of approval and continual assessment to ensure that the process is under control. This should be based on risk assessment and may include self-audit questionnaires where low-risk products are manufactured. The monitoring of the effectiveness of cleaning is likely to consist of visual assessment and the monitoring of complaints.

In-house laundering carried out on the company premises must be controlled. This is likely to be via HACCP-style principles, controls and validation data, such as monitoring of the temperature and detergent, specifying items not to be washed together, overseeing drying processes and visual inspection. The laundry will also be included in the programme of internal audits (clause 3.4.1).

 $Laundries\ (both\ in-house\ and\ contracted)\ must\ ensure\ that:$

- dirty and clean clothing is adequately segregated to ensure that recently laundered items are not re-contaminated
- the protective clothing is effectively cleaned (e.g. by the completion of microbiological validation and verification tests)
- cleaned clothes are protected from contamination until delivered to the site (e.g. through the use of covers or bags).

CLAUSE	REQUIREMENTS
	Home laundering may be deemed acceptable in low-risk operations such as produce packing or enclosed process areas where the clothing is worn primarily to protect the worker from the product (e.g. raw root vegetables). This needs to be controlled by written instructions to staff, to include how garments are to be washed (temperature, detergent, specifying items not to be washed together and drying instructions). Employees must be provided with a suitable means to safely transport washed garments from home to the workplace (sealable plastic bags or similar). There must be a defined responsibility within the company for monitoring the effectiveness of the system. This is typically achieved by visual inspection. There must also be a procedure and system for effectively dealing with any case where employees are unable to perform self-laundry, either through lack of diligence or through lack of facilities. This system must be capable of being brought into immediate effect once a problem has been identified.
	Home laundering still requires appropriate care and attention to ensure that potential pathogens on clothes worn for work are removed or killed. For example, clothes worn for work should be washed separately from other laundry in an automatic washing machine using the hottest temperature the material of the clothes will withstand and the 'full load' setting. When thoroughly dried, the clothes should be ironed with a hot iron to further heat-disinfect the clothes.
7.4.4	Protective clothing shall be changed at an appropriate frequency, based on risk.
Interpretation	Changing protective clothing Protective clothing needs to be changed at an appropriate frequency to ensure that clothing cannot become a source of product contamination. The frequency of changes must be based on risk (e.g. using visual inspections, swabbing or contact plates). For example, hairnets are changed daily or whenever they are removed.
7.4.5	If gloves are used, they shall be replaced regularly. Where appropriate, gloves shall be suitable for food use, of a disposable type, of a distinctive colour (blue where possible), be intact and not shed loose fibres.
Interpretation	Gloves Gloves are a potential source of foreign bodies; therefore, sufficient control procedures (such as regular inspection and replacement) need to be put in place to ensure they are intact and do not shed loose fibres. The company needs to consider the design of gloves and whether they need to be disposable, of food grade and of a visually distinct colour from the product (preferably blue).
7.4.6	Where items of personal protective clothing that are not suitable for laundering are provided (such as chain mail, gloves and aprons), these shall be cleaned and sanitised at a frequency based on risk.
Interpretation	Protective clothing that cannot be laundered A documented procedure must be developed for protective items that cannot be laundered, such as shoes,

 $chain\ mail\ (cut\text{-resistant},\ metallic\ PPE),\ gloves\ and\ aprons.\ The\ frequency\ of\ cleaning\ and\ sanitisation\ must$

be based on risk.

8 HIGH-RISK, HIGH-CARE AND AMBIENT HIGH-CARE PRODUCTION RISK ZONES

Where a site produces products that require handling in high-risk, high-care and/or ambient high-care production facilities (see Appendix 2 for the definition of products that require these facilities), all the relevant requirements from sections 1–7 of the Standard must be fulfilled in addition to the requirements in this section.

8.1 LAYOUT, PRODUCT FLOW AND SEGREGATION IN HIGH-RISK, HIGH-CARE AND AMBIENT HIGH-CARE ZONES

The site shall be able to demonstrate that production facilities and controls are suitable to prevent pathogen contamination of products.

Interpretation

Prevention of potential contamination with pathogens is of paramount importance in the production of safe food. One of the key ways of achieving this is to ensure the correct design (e.g. segregation) and control (e.g. restricted access) of areas of the site where open products, susceptible to contamination, are handled. The Standard defines these controls as production risk zones.

Where a site produces products that require handling in high-risk, high-care and/or ambient high-care production facilities (see Appendix 2 of the Standard for the definition of products that require these facilities), all the relevant requirements from sections 1–7 of the Standard must be fulfilled in addition to the requirements in this section.

BRC Global Standards has produced a specific guideline on high risk, high care and ambient high care, which explains the requirements and provides details of good practice. It may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).

CLAUSE	REQUIREMENTS
8.1.1	The map of the site (see clause 4.3.1) shall include areas (zones) where the product is at different levels of risk from contamination. The map shall show:
	 high-risk areas high-care areas ambient high-care areas low-risk areas enclosed product areas non-product areas.
	See Appendix 2 [of the Standard] for guidelines on defining the production risk zones.
	This zoning shall be taken into account when determining the prerequisite programmes for the particular areas of the site.
Interpretation	Designation of production wisk zones

Interpretation

Designation of production risk zones

Within any manufacturing facility there will be production areas where the product is more or less at risk from the general environment in which the process takes place. The objective of identifying on a factory plan the production risk zones is to ensure that the standards of environmental hygiene, particularly those concerning equipment, buildings, cleaning and personnel hygiene, are appropriate for the work being undertaken. It also allows product and personnel flows to be reviewed, to ensure they do not compromise product safety.

The Standard is based on six recognised zones:

- high-care and high-risk zones for chilled and ready-to-eat products
- ambient high-care zone for products where there is a risk of contamination with vegetative micro-organisms originating from raw materials and the products are stored in ambient conditions (rather than chilled or frozen)
- low-risk areas
- enclosed product areas (e.g. warehouse areas where products are fully enclosed within packaging; pipework or equipment, where product is fully enclosed within the equipment or pipework)
- non-product areas (i.e. areas such as offices, where products are not taken at any stage in their manufacture or storage).

CLAUSE

REQUIREMENTS

In recent years, there have been well-publicised food poisoning incidents associated with a wide range of products which had not previously been considered a concern (e.g. chocolate, peanut butter and cantaloupe melons). This reinforces the need for processors to understand their products thoroughly and configure their food safety systems accordingly, regardless of the zones in which they are produced.

It is important to note that the high-care, high-risk and ambient high-care production zones usually apply to only part of a factory's production processes; they typically follow a microbiological kill step and are maintained until the products are enclosed in packaging.

Where a product requires a high-risk or high-care production zone during its manufacture and initial packing, equivalent controls are expected for any subsequent handling or repacking operation where the product is open to the factory environment (i.e. the repacking site is expected to follow the high-risk or high-care requirements appropriate for the product).

8.1.2

Where high-risk areas are part of the manufacturing site, there shall be physical segregation between these areas and other parts of the site. Segregation shall take into account the flow of product, the nature of the materials (including packaging), the equipment, the personnel, the disposal of waste, the flow of air, the air quality, and the provision of utilities (including drains). The location of transfer points shall not compromise the segregation between high-risk areas and other areas of the factory. Practices shall be in place to minimise the risk of product contamination (e.g. the disinfection of materials on entry).

Interpretation

High-risk areas

High-risk areas require the highest levels of hygiene, working practices, design and fabrication of facilities and equipment to prevent product contamination from microbiological hazards.

High-risk areas must be fully separated areas with physical segregation in place between the high-risk area and other parts of the facility. The purpose of the physical segregation is to provide a self-contained area where uncovered (i.e. unprotected) high-risk products are handled after the microbiological kill step (e.g. thermal processing) until fully protected, usually by means of final packaging. The segregating barrier must be capable of minimising the risk of cross-contamination from:

- pathogens which may be present in a low-risk environment or on products or ingredients that have not received a full cook
- all people moving between the high-risk area and other areas except through designated changing areas
- the movement of all equipment, utensils or materials into the high-risk area except through designated ports with sanitising controls in place
- water or other liquids on the floor, washing into the high-risk area
- airborne contaminants (e.g. dust particles or water droplets).

The ideal barrier is a full wall separating the high-risk area from other areas. In assessing the suitability of a segregating barrier, a risk assessment should be carried out and documented.

Time segregation is not an acceptable alternative for high-risk areas, except for the transfer areas noted below. The location and operation of all transfer points must not compromise high-risk and low-risk segregation. For example, where raw materials or staff move into a high-risk area, consideration must be given to whether this introduces a contamination hazard; it may therefore require measures that involve:

- use of disinfection
- removal of outer packaging
- double-door ovens, blast chillers or freezers (i.e. those with a separate entrance and exit)
- controlled air flow (clause 8.2.2)
- changing the design of entrances and exits (e.g. roller lifting doors may represent a risk when raised, due to the fact they have been in contact with the floor and the difficulty in cleaning them effectively).

CLAUSE REQUIREMENTS

High-risk areas are expected to be self-contained and fully segregated. Best practice is that, where there is a cook step in the production of high-risk products, the cooker becomes the transfer point into the high-risk area via a double-door system (i.e. the cooker is loaded in the low-risk area and unloaded directly into the high-risk area). While new cooker installations and new-build sites must incorporate double-door cooking systems, many existing plants are equipped with single-door cookers and have established risk-based procedures for the loading and unloading of the cookers to prevent cross-contamination of cooked products. The Standard will, therefore, accept the use of single-door cooking systems where a thorough risk assessment has been completed as an interim measure prior to eventual upgrading. Operating practices must be consistently achievable, effective and prevent cross-contamination of cooked products.

The risk assessment must consider and control potential risk from:

- crossover between cooked and raw products in the unloading area
- operators and their clothing (e.g. handling of cooked products by operators who have previously worked with raw products)
- hand-contamination resulting from touching surfaces such as common equipment, cooker control panels and cooker door handles
- equipment used for transferring product in and out of cookers
- airborne contamination from low-risk processes (e.g. the loading and unloading area should be separate from the main low-risk processing area)
- the floor (e.g. contamination of the wheels of trolleys transferring cooked products to the high-risk area).

When cooked products are unloaded from the cooker they must be moved immediately to a designated high-risk area to meet the requirements of the Standard. The procedures in operation where single-door cookers are in use will be assessed by the auditor to ensure they are adequate, effective and understood by operators. The audit report will describe the procedures in place to protect the cooked products from contamination.

High-risk areas contain only components/foods which have undergone a cook or similar process to achieve typically a 6 log reduction for *Listeria*. Where a single area includes, by necessity, some components which have received a lesser kill, as well as fully cooked components (e.g. in a sandwich preparation area), this will be classed as high care.

8.1.3

Where high-care areas are part of the manufacturing site, there should be physical segregation between these areas and other parts of the site. Segregation shall take into account the flow of product, the nature of materials (including packaging), the equipment, the personnel, the disposal of waste, the flow of air, the air quality, and the provision of utilities (including drains). Where physical barriers are not in place, the site shall have undertaken a documented risk assessment of the potential for cross-contamination, and effective, validated processes shall be in place to protect products from contamination.

Interpretation

High-care areas

This clause is applicable to high-care areas (i.e. areas designed to a high standard, where practices are in place to minimise product contamination by pathogenic micro-organisms).

Vulnerable products and ingredients have, before entry to the high-care area, undergone a process to reduce any contamination by pathogenic bacteria (e.g. a chlorine wash of salad materials or an early cook step as in the pasteurisation of cream). It is important that the high-care area is effectively protected from contamination by low-risk zones. This is most effectively achieved through full physical segregation by means of walls which separate the high-care area from other factory areas.

Where a separate, fully walled-off area is not available, alternative procedures must be in place to segregate the high-care area. The segregating barrier must be capable of preventing the risk of cross-contamination from:

- unauthorised access and movement between high-care and other areas of the factory except through designated changing areas
- transfer of materials, utensils or equipment except through designated ports with sanitising controls in place
- microbiological contamination which may be present in a low-risk environment
- airborne contaminants (e.g. dust particles or water droplets).

CLAUSE

REQUIREMENTS

The segregating barrier may include time or space separation, control of movement or other restrictions. In assessing the suitability of the segregating barrier, a risk assessment must be carried out and documented. The method employed must be validated to demonstrate that the controls are effective in preventing cross-contamination. The auditor will critically examine the arrangements to ensure that potential risks for contamination have been addressed and that the alternative controls are consistently workable before the solution is considered acceptable. (This will be recorded in the audit report.)

Where the solution is time segregation, the changeover between standard and high-care operations should be as infrequent as possible, as it is unlikely that a sufficient standard of cleaning could be reached if changes occur frequently during the day. Fully validated procedures to change the area from low-risk to high-care are required. These activities need to be taken into account when scheduling production, to ensure effective transformation of the area, including personnel. If the same personnel are responsible for the area during low-risk and high-care operations, they must undergo a complete change of protective clothing.

Where product characteristics meet the description of high care but the systems are fully enclosed (e.g. dairies filling cartons with milk), the production area is considered an enclosed product area. However, additional precautions are required when breaking into the lines or entering filler equipment (e.g. for maintenance, to free product blockage or for cleaning). Wherever equipment is entered, the necessary hygiene requirements must be completed before operations can recommence.

It is expected that newly built factories will employ full wall segregation where high-care facilities are required.

8.1.4

Where ambient high-care areas are required, a documented risk assessment shall be completed to determine the risk of cross-contamination with pathogens. The risk assessment shall take into account the potential sources of microbiological contamination and include:

- the raw materials and products
- the flow of raw materials, packaging, products, equipment, personnel and waste
- air flow and quality
- the provision and location of utilities (including drains).

Effective processes shall be in place to protect the final product from microbiological contamination. These processes may include segregation, management of process flow or other controls.

Interpretation

Ambient high-care areas

This clause is applicable to ambient high-care areas (i.e. areas designed to a high standard, where practices are in place to minimise product contamination by pathogenic micro-organisms).

Ambient products that are handled in these areas are vulnerable, as vegetative pathogens are known to survive adverse conditions and may subsequently represent a potential food poisoning risk.

Products which require handling in ambient high-care areas are those which meet all of the following criteria:

- they contain a raw material that is prone to contamination with vegetative pathogens (e.g. Salmonella species)
- the production process includes a process step which removes or reduces the pathogen (e.g. a
 microbiological kill step). (Where there is no effective step in the on-site processes, it is assumed that any
 risk associated with the raw material is controlled as part of the raw material risk assessment and goods
 receipt processes.)
- the finished products are stored at ambient temperatures (i.e. above 5°C)
- the finished products are ready to eat or ready to heat or, on the basis of known consumer use, are likely to be eaten without adequate cooking
- the finished products are such that vegetative pathogens could survive and grow in normal use, subsequently causing food poisoning, or are of a nature (e.g. fatty foods) that enables food poisoning to result from a very low level of contamination with a pathogen.

CLAUSE **REQUIREMENTS**

Where products fall into the ambient high-care category, the site should have conducted a risk assessment to identify the potential risks of cross-contamination (e.g., locations where cross-contamination could occur) and introduced procedures and processes to manage these potential risks. The procedures required will be dependent on the level of risk, but could, for example, include:

- segregation normally this would be physical separation; however, time segregation would be permitted where the site can demonstrate that processes effectively minimise the risk of contamination
- management of the process flow ensuring a logical (and usually linear process) so that implicated raw materials are not in the same area as final product (or intermediates that have been through the process to remove or reduce micro-organisms).

Additional information on ambient high-care areas can be found in Appendix 2 of the Standard.

DITTI DING EADDIC IN HIGH-DISK AND HIGH-CADE TONES

CLAUSE	REQUIREMENTS
8.2.1	Where sites include high-risk or high-care facilities, there shall be a map of the drains for these areas which shows the direction of flow and the location of any equipment fitted to prevent the back-up of waste water. The flow from drains shall not present a risk of contamination to the high-risk/care area.
Interpretation	Drainage for high-risk and high-care areas The flow of drains must not present a risk of contamination of the high-risk/high-care areas. There must be a plan of the drains for these areas which shows the direction of flow and location of any equipment fitted to prevent the back-up of waste water. For example, drains should flow from high-risk to low-risk areas and include suitable barriers such as totally separate drains that are not connected to other areas of the site. They should also feature non-return or anti-syphon valves, and one-way traps or a sufficient drop to ensure flow.
	The map does not need to be a separate document. It can be combined with a map of the zones of the site if this is more convenient.
	Good practice is for the site to have procedures in place for the action to be taken in the event of a failure of the drain traps or if water backs up into the high-risk or high-care areas. This should be more than just mopping up and then continuing production, as the clause requires that the drains must not become a risk of contamination. A full clean including, for example, microbiological swabbing, may be required to reinstate and confirm the status of the high-risk area.
8.2.2	High-risk areas shall be supplied with sufficient changes of filtered air. The filter specification used and frequency of air changes shall be documented, based on a risk assessment that takes into account the source of the air and the requirement to maintain a positive air pressure relative to the surrounding areas.
Interpretation	Ventilation for high-risk areas High-risk areas must be supplied with sufficient changes of filtered air. Therefore a risk assessment must be completed, with the aim of ensuring that the air introduced will not contain micro-organisms of concern and will not be a source of additional contamination (e.g., through the formation of airborne water droplets).

will not be a source of additional contamination (e.g. through the formation of airborne water droplets). The following criteria should be considered:

- the source of air. The air inlet needs to be located to minimise intake of contaminated air (at a minimum, it should be upwind of potential contaminants such as dust and chemical vapours)
- the frequency of air changes
- the specification of filter used. There is no absolute global standard for the filters used in specific food industry applications; the grade required will depend on the source of the air and the length of time of exposure of high-risk products/ingredients
- the frequency of replacement of filters
- the need to maintain positive pressure compared with adjacent areas, particularly where there is an interface with low-risk areas.

CLAUSE	REQUIREMENTS
	The effectiveness of the system employed should be checked by the use of periodic sampling of air microbiological quality.
	While there is no specific requirement for an over-pressure of air in high-risk areas, good practice is for the ventilation system to be in balance, so that there is no large movement of air from low-risk into high-risk areas.
	Where air socks are used for high-risk areas, they should be identifiable and kept separate from those for other areas.

8.3 MAINTENANCE IN HIGH-RISK AND HIGH-CARE ZONES

CLAUSE	REQUIREMENTS
8.3.1	Maintenance activities undertaken in high-risk and high-care areas shall respect the segregation requirements of the area. Wherever possible, tools and equipment shall be dedicated for use in that area and etained in the same.
Interpretation	Maintenance in high-risk and high-care areas It is important that maintenance activities do not result in microbiological contamination of high-risk or high-care areas. Tools that are frequently needed in the area (e.g. spanners) should be dedicated to the area and not removed from there. Where specialist tools or equipment need to be brought into an area for a specific task, then mechanisms should be in place to ensure that this does not result in contamination (e.g. cleaning equipment before entry and post-maintenance cleaning of the high-risk or high-care area).
8.3.2	Where equipment is removed from the high-risk or high-care area, the site shall have a procedure to ensure the cleanliness and removal of contamination hazards before being accepted back into the area.
	Records of acceptance back into the area shall be maintained.
Interpretation	Movement of equipment Some equipment is moved from place to place in order to be used in different areas. Where this occurs, the site must take steps to ensure that re-introduction to those areas does not compromise the conditions (i.e. the equipment is suitably clean and will not be a source of contamination). The auditor will expect to see a procedure that addresses the re-introduction of equipment to a high-risk or
	high-care area, as well as evidence of adherence to this procedure where equipment has been moved.
8.3.3	Where portable equipment (e.g. handheld devices) is used in high-risk or high-care areas, these items shall either be:
	visually distinctive and dedicated for use in that area
	or
	have specific procedures (e.g. a full clean) to ensure that their use does not result in contamination.
Interpretation	Portable equipment Systems must ensure that the use or transportation of small portable equipment, such as hand-held devices, cannot become the source of pathogen contamination.
	Good practice is for these items to be dedicated to the designated area. Where this is not practical, then specific procedures must be in place to prevent contamination (e.g. movement only through designated routes with associated cleaning or sanitising controls).

8.4 STAFF FACILITIES FOR HIGH-RISK AND HIGH-CARE ZONES

CLAUSE REQUIREMENTS Where an operation includes a high-risk or high-care area, personnel shall enter via a specially designated 8.4.1 changing facility at the entrance to the area. The changing facilities shall incorporate the following: clear instructions for the order of changing into and out of dedicated protective clothes to prevent the contamination of clean clothing • protective clothing that is visually distinct from that worn in other areas and which shall not be worn outside the area a hand-washing routine during the changing procedure to prevent contamination of the clean clothing (i.e. hand-washing after hair covering and footwear have been put on, but before handling clean protective clothing) • provision and use of hand-washing and disinfection facilities. At a minimum these shall be: prior to entry for high-risk areas on entry for high-care areas dedicated site footwear that is provided by the site and which shall not be worn outside the factory an effective control of footwear to prevent the introduction of pathogens into the area. Control may be by segregation and a controlled change of footwear before entering the area (such as a barrier or bench system) or by the use of controlled and managed boot-wash facilities where these demonstrably provide an effective control of footwear to prevent the introduction of pathogens into the area. A programme of environmental monitoring shall be used to assess the effectiveness of footwear controls. Interpretation High-risk and high-care area changing facilities The objective of this clause is to ensure that protective clothing, once applied, is not contaminated before entry into the high-risk or high-care area. For facilities with high-risk or high-care areas, personnel must enter these areas via a specific, designated changing facility (i.e. separate from other, lower-risk changing areas) and must follow documented instructions to: apply specific dedicated protective clothing which is visually distinct (e.g. a different colour or style), including clean overalls, headwear and footwear

- apply clothing in a given order, for example:
- put on hair covering
- remove shoes
- step over barrier (see below)
- put on dedicated footwear
- wash hands
- put on coat or overalls
- wash and sanitise hands
- wash hands during the changing procedure.

When personnel leave the high-risk or high care area, there must be clear instructions for changing out of protective clothing to ensure that the overall is removed before handling shoes or hair covering. (This is particularly important where the clothing is to be re-used; for example, if someone is temporarily leaving the area for lunch or a break.)

Footwear to be worn in areas must be dedicated to the factory (i.e. factory-issued and not worn outside the factory). The footwear should also be captive to the area (i.e. worn only in the high-risk area). The changing area must be laid out with an effective system to differentiate areas for wearing high-risk footwear (e.g. by the use of a barrier or bench system).

By exception, boot-wash facilities may be used instead of changing into captive footwear dedicated to the area. Boot-wash facilities at the entrance to an area will be accepted where this is effectively controlled, managed and validated to prevent the introduction of pathogens. The site must have undertaken a risk assessment to identify the suitability of the boot-wash facilities and established controls to manage the effective sanitation of footwear. The controls must have been validated by microbiological swabbing of footwear, floors and drains in the high-risk area to demonstrate the absence of pathogens (e.g. Listeria species).

CLAUSE

REQUIREMENTS

For controls to be effective, they should include the following criteria:

- The footwear must be company-issued and of a design which is easily cleaned (i.e. smooth upper surfaces and cleats on soles sufficiently spaced so as not to trap dirt which may not be easily removed by boot-wash equipment).
- The potential for cross-contamination of boots prior to boot-washing must be considered.
- Permitted areas where footwear can be worn prior to entry to an area must be clearly defined.
 For example, the same footwear must not be worn outside the facility or in low-risk processing areas prior to entering the area.
- The boot-wash equipment shall be suitably designed, well maintained and demonstrably effective in cleaning and sanitising the footwear.
- The minimum cleaning time and concentrations of detergent and sanitiser must be determined, monitored, documented and controlled to ensure effective cleaning of footwear.
- A cleaning schedule for the cleaning of the boot-wash facility and equipment should be in place to ensure that the boot-wash does not become a source or vector of microbiological contamination.

Consideration must be given to the location of the boot-wash facilities (i.e. at the entrance to the high-risk area but at a suitable distance from production).

Environmental monitoring programmes must include specific reference to high-risk and high-care areas (e.g. footwear, floors and drains) to demonstrate the continued effectiveness of the footwear control.

Records shall be maintained of detergent/sanitiser checks, and of the effectiveness of the boot-wash facilities.

All visitors and contractors entering the area will need dedicated footwear; shoe covers are not satisfactory for high-risk or high-care areas as they rarely cover the whole shoe and often tear or fragment during use, resulting in a lack of protection and the potential to become foreign-body risks.

High-risk and high-care clothing must not be worn outside the designated area.

The objective of the use of dedicated clothing is to prevent the potential contamination of products. If the cleaning team (or indeed anyone else, such as engineers or visitors) enter an area while production is in progress or open products are present, they must follow the same clothing rules as production staff. If cleaning occurs outside production time, the absolute rules on protective clothing may be adapted but must ensure that the production area is left in a condition, after cleaning, such that no microbiological risks have been introduced by the cleaners or equipment used. The same principles apply to engineers undertaking maintenance work (which should be followed by cleaning to restore the microbiological security of the area).

Wherever practical, auditors will be expected to observe the cleaning in high-risk areas to ensure that the practices used are effective and that controls are in place to prevent this activity introducing new risks.

8.5 HOUSEKEEPING AND HYGIENE IN HIGH-RISK AND HIGH-CARE ZONES

CLAUSE	REQUIREMENTS
8.5.1	Environmental cleaning procedures in high-care/high-risk areas shall, at a minimum, include:
	 responsibility for cleaning item/area to be cleaned frequency of cleaning method of cleaning, including dismantling equipment for cleaning purposes where required cleaning chemicals and concentrations cleaning materials to be used cleaning records and responsibility for verification.
	The frequency and methods of cleaning shall be based on risk, and the procedures shall be implemented to ensure that appropriate standards of cleaning are achieved.

CLAUSE **REQUIREMENTS** Interpretation **Documented cleaning procedures** Documented cleaning procedures must be in place to ensure consistent and effective cleaning and as a quide for training purposes. Cleaning procedures for these areas need to include information on the: staff responsible equipment, building and plant to be cleaned frequency of cleaning • methods to be used (see below) • materials to be used (e.g. required chemicals and concentrations – good practice is to follow the cleaning chemical manufacturer's instructions relating to concentration, temperature and contact time) • equipment to be used, such as hoses or brushes instructions on the correct/safe dismantling of equipment where this is required for cleaning purposes records to be kept responsibility for verification • methods of verification (e.g. visual inspection, ATP monitoring, microbiological swabs or allergen swabs). Where equipment requires different levels of cleaning (e.g. between products, or between daily and weekly cleans), each requirement should be clearly detailed. It may be useful to include photographs in the instructions. The procedures need to be reviewed and updated when changes occur to the areas to be cleaned. Microbiological limits for acceptable and unacceptable cleaning performance shall be defined for high-risk/ 8.5.2 high-care production risk zones. These limits shall be based on the potential hazards relevant to the product or processing area. Therefore, acceptable levels of cleaning may be defined by visual appearance, ATP bioluminescence techniques (see glossary), microbiological testing, allergen testing or chemical testing as appropriate. The site shall define the corrective action to be taken when monitored results are outside of the acceptable limits. Where cleaning procedures are part of a defined prerequisite plan to control the risk of a specific hazard, the cleaning and disinfection procedures and frequencies shall be validated and records maintained. This shall include the risk from cleaning chemical residues on food contact surfaces. Interpretation Cleaning performance limits At a minimum, limits of acceptable and unacceptable cleaning performance must be defined for environmental cleaning (i.e. the factory environment) in high-risk and high-care areas. The limits need to be based on the risk, and this should be used for assessing whether the cleaning undertaken is of an acceptable standard. Acceptable limits may be based on visual inspection, ATP monitoring or specific analysis such as microbiological testing. Where the cleaning procedure forms part of a defined prerequisite (clause 2.2.1), designed to manage a specific hazard, then the procedure must be validated to confirm that the specified cleaning method, chemicals and concentrations are capable of consistently achieving the level of performance required. Records of validation must be maintained. Note that the requirements in this section are in addition to relevant requirements in section 4.11. Equipment used for cleaning in high-care and high-risk areas shall be visually distinctive and dedicated for 8.5.3 use in that area. Interpretation Cleaning equipment Equipment used for cleaning high-care or high-risk areas must be dedicated for use in that area, and therefore retained in the area (i.e. it should not be removed from the area for cleaning or any other purpose). It should also be visually distinct (e.g. colour-coded) from cleaning equipment used in other areas.

Where it is not possible to effectively clean equipment in the high-risk or high-care area, then a suitable transfer control should be in operation (e.g. heating or disinfection prior to transfer back into the high-risk or high-care area).

The cleaning equipment used in high-risk and high-care areas should be fit for purpose; for example, high-pressure hoses are not normally used in high-risk areas because of the potential to create aerosols and move debris.

8.6 WASTE/WASTE DISPOSAL IN HIGH-RISK, HIGH-CARE ZONES

CLAUSE	REQUIREMENTS
8.6.1	Waste disposal systems shall ensure that the risk of contamination of products is minimised through the control of potential cross-contamination.
	Risk assessment shall consider the movement and flow of waste and waste containers. For example, waste bins should be dedicated to either high-risk or high-care areas and not be moved between different production risk zones.
Interpretation	Waste disposal in high-risk or high-care areas Risk assessment must consider the movement and flow of waste. For example, bins must be dedicated to either high-risk or low-risk areas and must not move between the two. Waste from high-risk and high care areas should be transferred to other containers at the transfer point.

8.7 PROTECTIVE CLOTHING IN HIGH-RISK AND HIGH-CARE ZONES

CLAUSE	REQUIREMENTS
8.7.1	Laundering of protective clothing for high-risk and high-care areas shall be by an approved contracted or in-house laundry using defined criteria to validate the effectiveness of the laundering process. The laundry must operate procedures which ensure:
	 adequate segregation between dirty and cleaned clothes adequate segregation between clothes for high-risk, high-care and low-risk areas etc. effective cleaning of the protective clothing commercial sterilisation of the protective clothing following the washing and drying process protection of the cleaned clothes from contamination until use (e.g. by the use of covers or bags).
Interpretation	Laundry Protective clothing may be cleaned by contracting the services of a specialised laundry, or by laundering in-house.
	External contracted services must be incorporated within the company's purchasing supplier approval programme (clause 3.5.3.1) and have systems of approval and continual assessment to ensure that the process is under control.
	In-house laundering carried out on the company premises must be controlled. This is likely to be via HACCP-style principles, controls and validation data, such as monitoring of the temperature and detergent, specifying items not to be washed together, overseeing drying processes and visual inspection. The laundry will also be included in the programme of internal audits (clause 3.4.1).
	Laundries (both in-house and contracted) must ensure that:
	 dirty and clean clothing is adequately segregated to ensure that recently laundered items are not re-contaminated the protective clothing is effectively cleaned (e.g. by the completion of microbiological validation and verification tests)
	 clothing is commercially sterile following the washing and drying process. 'Commercially sterile' means the removal of vegetative forms of micro-organisms associated with food poisoning and/or spoilage. To achieve this, a garment should be laundered at a temperature no lower than 65°C for a minimum of 10 minutes, or laundered at a temperature no lower than 71°C for a minimum of 3 minutes, or in accordance with local regulatory requirements
	 cleaned clothes are protected from contamination (e.g. through the use of covers or bags) until delivered to the appropriate area of the site (e.g. specific storage for clean protective clothing in the high-risk changing facility).
	Home laundering is not considered suitable for protective clothing used in high-risk or high-care areas.
	BRC Global Standards has published a guide to contracted laundries which may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate

(www.brcparticipate.com).

CLAUSE	REQUIREMENTS
8.7.2	Where protective clothing for high-care or high-risk areas is cleaned by a contracted or in-house laundry, the laundry shall be audited either directly or by a third party. The frequency of these audits shall be based on risk.
Interpretation	Protective clothing for high-risk and high-care areas The company will need to assess and monitor the laundry (e.g. through visual inspection, regular audits and a complaints procedure) to ensure that the processes in place for the cleaning of high-risk and high-care clothing are maintained and kept consistently under control.
	The audits of the laundry can be completed either directly (i.e. by the site) or by a suitable third party. The frequency of the audits should be based on risk.
8.7.3	Protective clothing for use in high-risk and high-care areas shall be changed at an appropriate frequency based on risk, and at a minimum daily.
Interpretation	Changing protective clothing Protective clothing needs to be changed at an appropriate frequency to ensure that clothing cannot become a source of product contamination.
	Protective clothing worn in high-risk or high-care areas must be changed at least daily and hairnets changed daily or whenever removed (e.g. when leaving the area).
	Where risk assessment determines that more frequent changing is appropriate, the site must ensure this occurs. The auditor will expect to see the risk assessment, documented protective clothing procedures, and application of the procedures in practice.
	Spare protective clothing should be available on demand should currently used items become soiled.

9 REQUIREMENTS FOR TRADED PRODUCTS

Where a site purchases and sells food products that would normally fall within the scope of the Standard and are stored at the site's facilities, but which are not manufactured, further processed or packed at the site being audited, the site's management of these products shall be covered by the requirements in this section.

All the relevant requirements from sections 1 to 8 must also be fulfilled in addition to the requirements outlined in this section.

9.1 APPROVAL AND PERFORMANCE MONITORING OF MANUFACTURERS/PACKERS OF TRADED FOOD PRODUCTS

The company shall operate procedures for approval of the last manufacturer or packer of food products which are traded to ensure that traded food products are safe, legal and manufactured in accordance with any defined product specifications.

Interpretation

All traded food products brought onto the site must be sourced from approved suppliers who are regularly monitored for their performance. The risk assessment process should focus more on those products and suppliers that present a greater risk (in terms of safety, authenticity, legality and quality).

CLAUSE	REQUIREMENTS
9.1.1	The company shall have a documented supplier approval procedure which identifies the process for initial and ongoing approval of suppliers and the manufacturer/processor of each product traded. The requirements shall be based on the results of a risk assessment which shall include consideration of:
	 the nature of the product and associated risks customer-specific requirements legislative requirements in the country of sale or importation of the product source or country of origin potential for adulteration or fraud potential risks in the supply chain to the point of receipt of the goods by the company the brand identity of products (i.e. customer own brand or branded product).
Interpretation	Supplier approval and monitoring system: risk assessment For easier management, sites could choose to integrate the approval process for their traded products suppliers with that for their raw materials suppliers, or organise the traded products suppliers as a separate workstream.
	All suppliers of traded products must be evaluated on the basis of a risk assessment for their ability to meet the specifications of the products they are supplying to the certificated site; in particular the requirements for safety, quality and legality. For example, the assessment should consider:
	 known hazards associated with the product provided (e.g. microbiological, chemical or foreign-body risks). Access to reference information and an awareness of emerging food issues are essential to ensure all known risks are assessed (see clause 1.1.8). customer or legislative requirements (e.g. suppliers may be specified by customers, but this does not negate the need for risk assessment). Legislation in the country of expected sale should be considered geographic origins (products from particular countries may carry a greater risk because of environmental conditions, more relaxed local legal requirements or a less developed food safety culture) the potential for fraudulent activity or food defence issues in the supply chain (e.g. undeclared additions,
	dilution or substitution of the raw material or a component of it). Additional focus must be placed on products where claims are being made (e.g. organic or suitable for
	allergy sufferers). Suppliers and their control systems must be assessed robustly to ensure compliance with the requirements.
	The outcome of this activity must also be considered when assessing the requirements for supplier approval and monitoring procedures (clause 9.1.2).

CLAUSE **REQUIREMENTS** The company shall have a procedure for the initial and ongoing approval of manufacturers of products. 9.1.2 This approval procedure shall be based on risk and include either one or a combination of: • a valid certification to the applicable BRC Global Standard or GFSI-benchmarked standard. The scope of the certification shall include the products purchased supplier audits, with a scope to include product safety, traceability, HACCP review and good manufacturing practices, undertaken by an experienced and demonstrably competent product safety auditor. Where this supplier audit is completed by a second or third party, the company shall be able to: demonstrate the competency of the auditor - confirm that the scope of the audit includes product safety, traceability, HACCP review and good manufacturing practices obtain and review a copy of the full audit report or • where a valid risk-based justification is provided and the supplier is assessed as low risk only, a completed supplier questionnaire may be used for initial approval. The questionnaire shall have a scope that includes product safety, traceability, HACCP review and good manufacturing practices, and it shall have been reviewed and verified by a demonstrably competent person.

Interpretation

Supplier approval and monitoring system: approval procedure

The company must document its procedure for supplier approval and monitoring. This needs to include the methods of approval, frequency of monitoring, staff responsibilities and how the process will be managed.

Approval will be dependent on the product and the risks associated with it (the output of clause 3.5.1.1) and will include one or more of the following activities:

- certification to the relevant BRC Global Standards scheme (such as food safety, packaging, storage and distribution, or agents and brokers) or a GFSI-benchmarked scheme. The site must confirm the validity of the certification. This will include:
 - confirmation of the certification status (this could be confirmed on an independent database; for BRC Global Standards it can be confirmed at www.brcdirectory.com). Photocopies of certificates are not recommended and on their own are not considered suitable validation of certification status.
 During the BRC Global Standards audit the site may be asked to demonstrate its validation process
 - confirmation that the certification remains up to date (e.g. by receiving confirmation of successful completion of the recertification process or by recording certificate expiry dates and completing checks for ongoing certification)
 - confirmation that the raw materials are within the scope of the certification.
- a successful site audit which at a minimum covers product safety, traceability, HACCP and good
 manufacturing processes. This audit must be completed by an appropriately experienced and
 competent auditor (i.e. someone who has completed training in auditing techniques, has experience of
 auditing, and has knowledge of the product, ingredient or processes being audited). Non-conformities
 should be addressed (e.g. in an agreed action with timescales) unless they are critical to product safety
 or legality, in which case supply should not be permitted until non-conformities have been satisfactorily
 addressed. If the supplier is audited to a standard that is not GFSI-benchmarked, this may be acceptable
 providing that:
 - the scope of the audit meets the requirements of the Standard
 - the site has a copy of the full audit report (not just a certificate)
 - the site can demonstrate the competence of the auditor.

Where the risk assessment (completed as part of this clause) indicates that a supplier is low risk (because of the history of trading with the site, the nature of the products traded etc.), the completion of a supplier questionnaire with a focus on food safety and quality may be sufficient. If a supplier questionnaire is the only mechanism used to assess a supplier (i.e. there are no additional activities such as supplier audits), then it is important that the questionnaire (and the replies from the supplier) contains all the relevant information to allow the site to confidently make a decision on approval.

The auditor will expect to see, and will challenge, any risk assessments that determine that suppliers have been deemed to be low risk.

CLAUSE	REQUIREMENTS
9.1.3	Records shall be maintained of the manufacturer's/packer's approval process, including audit reports or verified certificates confirming the product safety status of the manufacturing/packing sites supplying the products traded. There shall be a process of review and records of follow-up of any issues identified at the manufacturing/packing sites with the potential to affect food products traded by the company.
Interpretation	Records of approval The site is required to maintain records of the approval methods along with the evidence used to approve that supplier.
	Approval and associated risk assessments must be up to date and the site should therefore review the supplier assessment whenever there is an issue at the manufacturing site.
9.1.4	There shall be a process for the ongoing review of manufacturers/packers, based on risk and using defined performance criteria, which may include complaints, results of any product tests, regulatory warnings/alerts, customer rejections or feedback. The process shall be fully implemented.
	Where approval is based on questionnaires, these shall be reissued at least every 3 years and suppliers shall be required to notify the site of any significant changes in the interim, including any change in certification status.
	Records of the review shall be kept.
Interpretation	Ongoing monitoring As much as it is important to know how and why suppliers are approved, it is also vital to ensure that ongoing approval is justified. The site is free to determine how it confers continuing approval on its suppliers, but it must ensure that the supplier's performance is matching its own food safety objectives.
	The defined performance criteria can be determined by the site and these may include:
	 punctuality of deliveries against planned delivery times incidences of contamination quality of material supplied.
	Frequency of ongoing approval is also left for the site to determine. The site should be able to demonstrate to the auditor that the monitoring it uses is appropriate, justified and risk-based. Examples of different types of monitoring will be required.

9.2 SPECIFICATIONS

Specifications or information to meet legal requirements and assist customers in the safe usage of the product shall be maintained and available to customers.

Interpretation

A finished product specification must exist for all traded food products to ensure that legislation requirements and customer expectations are met.

CLAUSE	REQUIREMENTS
9.2.1	Specifications shall be available for all products. These shall either be in the agreed format as supplied by the customer or, where this is not specified, include key data to meet legal requirements and assist the customer in the safe usage of the product.
	Specifications may be in the form of a printed or electronic document, or part of an online specification system.
Interpretation	Product specifications Specifications for all products must be provided and adequately detailed. They must include the defined data for all parameters critical to the safety, legality and quality of the product. The specifications may be in the format provided by the supplier or in the company's own format, as long as the information controlling the product's safety, quality and legality are clearly defined.

CLAUSE	REQUIREMENTS
9.2.2	The company shall seek formal agreement of the specifications with relevant parties. Where specifications are not formally agreed, the company shall be able to demonstrate that it has taken steps to ensure formal agreement is in place.
Interpretation	Formal agreement of specifications Customer-branded finished product specifications must be formally agreed and, wherever possible, signed by both parties. However, where signature or approval is not formally available, proof that specifications have been issued (such as an email request for formal acknowledgement or specifications) is required. In this situation the site must be able to demonstrate it is following a formal process agreed with its suppliers.
9.2.3	Companies shall operate demonstrable processes to ensure that any customer-specified requirements are met. This may be by inclusion of customer requirements within buying specifications or by undertaking further work on the purchased product to meet the customer's specification (e.g. sorting or grading of product).
Interpretation	Customer requirements Many customers have specific requirements relating to product safety, quality and legality and the site needs to ensure that it is aware of and understands them (e.g. by retaining copies of relevant customer's policy documents or service-level agreements).
	The site must also have a mechanism for ensuring these requirements are met. For example, by communicating with the relevant suppliers of products, by incorporating the information in specifications, or by recording minutes of review meetings in which the requirements are agreed with the supplier.
	Occasionally the site may arrange for additional work to be completed on the product before it is sent to the customer. Good practice is to ensure that any changes to the requirements are communicated and agreed in a timely manner.
9.2.4	Specification review shall be sufficiently frequent to ensure that data is current or at a minimum every 3 years, taking into account product changes, suppliers, regulations and other risks.
	Reviews and changes shall be documented.
Interpretation	Review of specifications Specifications must be reviewed whenever changes occur to the product, process or formulation.
	Where no known changes have occurred, the specifications should be reviewed at least every 3 years, or more frequently if required, to ensure they remain completely up to date and accurate. Evidence that a review has been completed needs to be available and this should be achieved by the addition of a signature and date to the specification or by the use of a matrix showing specifications and the latest review date and reviewer.
	The control of the amendment and approval of specifications should be laid down in a documented procedure. The procedure should also detail who can approve the amendments.
	Some sites, companies or customers use cloud-based services which are able to notify the user when there has been a change to the data. In this case the site should have a mechanism to review the specification/change to understand whether there is any impact on the product.

9.3 PRODUCT INSPECTION AND LABORATORY TESTING

The site shall operate processes to ensure that the products received comply with buying specifications and that the supplied product is in accordance with any customer specification.

Interpretation

The company needs to identify and schedule critical inspections and analyses for its traded food products. These may include:

- identification of known product safety risks associated with the product type
- assessment of legal requirements, particularly those associated with the country of intended sale (where known)
- assurance of product integrity (e.g. where a genuine risk of adulteration, substitution or fraud has been identified during a vulnerability assessment; see clause 5.4.2)
- inspection of quality attributes (e.g. where these form part of a specification agreed with the customer).

The frequency and types of inspection and analysis are not prescribed by the Standard but should be risk-based and specific to the type of products.

CLAUSE	REQUIREMENTS
9.3.1	The site shall have a product sampling or assurance programme to verify that the products are in accordance with buying specifications and meet legal and safety requirements.
	Where verification is based on sampling, the sample rate and assessment process shall be risk-based.
	Records of the results of assessments or analysis shall be maintained.
Interpretation	Product test schedules The company needs to have a documented schedule of product sampling or assurance tests which are carried out on the products.
	The objective of product tests is to ensure that products are manufactured to specification and in compliance with safety and legislative requirements. The frequency and type of product tests should be based on risk and on any particular customer requirements. They may, for example, include:
	 quality tests (e.g. appearance, colour or organoleptic qualities) safety tests (e.g. chemical or microbiological) or tests to confirm legality (e.g. country of origin or species) customer-specific requirements based on the specification or the customer's contract with the company.
	The site should be able to explain and justify the basis for the frequency of tests with reference to historical or scientific information as appropriate.
	Good practice is for the test method and specifications to be documented. Where the results of a test are not quantitative, colour standards or reference samples must be used to provide a reference point for the test results (i.e. to define pass/fail criteria).
	Where tests are completed on site, the location of the testing should be considered; for example, laboratory facilities will need appropriate siting and controls (clause 5.6.2.2). Organoleptic tests should be completed in a designated area and not on the production line.
9.3.2	Where verification of conformity is provided by the supplier (e.g. certificates of conformity or analysis), the level of confidence in the information provided shall be supported by commissioning periodic independent product analysis.
Interpretation	Verification of conformity The company must be able to demonstrate that each product meets legal requirements for its use.
	Products are often traded with supporting evidence provided by the supplier (e.g. in the form of a certificate of analysis or certificate of conformity relating to the specific batch or lot of product supplied). Where these are used, they must be supported by procedures to substantiate the reliability of the information using independent product analysis.
	The frequency of this periodic assessment should be based on risk assessment that considers the likelihood of an error occurring and the potential consequences if the error occurred.

CLAUSE	REQUIREMENTS
9.3.3	Where claims are made about the products being handled, including the provenance, chain of custody and assured or 'identity preserved' status of a product or raw materials used, supporting information shall be available from the supplier or independently to verify the claim.
Interpretation	Status verification of products The types of claim covered by this clause relate to the provenance of products that differentiates it from the norm. Such a claim may be made either on the product label for the consumer or in business-to-business communication. The types of claim include:
	 varietal claims (e.g. basmati rice, Aberdeen Angus beef, Bramley apples and cod fish cakes) origin claims (e.g. Madagascan vanilla and Florida grapefruit) assurance claims (e.g. GlobalG.A.P., Red Tractor, Marine Stewardship, dolphin-friendly tuna and sustainable palm oil) identity-preserved claims (e.g. GMO (genetically modified organism) free).
	It is the responsibility of the site to obtain sufficient supporting information to ensure that the product claims are genuine and proven.
	For many assurance schemes, such as GlobalG.A.P., it is possible to check the assurance status and the scope of products of the supplier on a database. Reliance solely on a declaration from a supplier will not be sufficient. Where claims relate to variety or species (e.g. varieties of fruit), examination of visual characteristics may suffice. However, for claims where visual analysis is not possible (e.g. block frozen fish), certificates of analysis and periodic sample analysis will be required.
9.3.4	Where the company undertakes or subcontracts analyses which are critical to product safety or legality, the laboratory or subcontractors shall have gained recognised laboratory accreditation or operate in accordance with the requirements and principles of ISO 17025. Documented justification shall be available where non-accredited test methods are used.
Interpretation	Analyses critical to safety and legality This clause applies to tests which are critical to product safety or legality. Results from such tests must be credible and may be called upon in a court of law.
	The company needs to identify which tests are critical to product safety or legality, such as compliance with label claims/declarations (e.g. nutritional claims, alcohol content) and tests for contamination (e.g. by pesticides, aflatoxins).
	Note that while the laboratory itself may have accreditation, the actual test methods must also be accredited. Any method of analysis that is not accredited needs justification as to why it was used (e.g. it may be a method for which no accreditation is yet available). Where critical tests are carried out by non-accredited laboratories (either contracted or on-site laboratories), there must be suitable documentary assurances that the laboratory is working to the requirements and principles of ISO 17025. This must include confirmation of the laboratory's procedures to meet the following general principles:
	 staff competency and documented training documented test methodology based on accepted standards equipment that is fit for purpose and appropriately calibrated a documented quality assurance programme, including paired testing, ring testing etc. completion of internal audits of the laboratory's operation.
9.3.5	Test and inspection results shall be retained and reviewed to identify trends. Appropriate actions shall be implemented promptly to address any unsatisfactory results or trends.
Interpretation	Reviewing test results Systems of recording and review must be formalised and must include evidence of actions taken on identified trends, or where unsatisfactory results have been recorded. The use of graphs or charts of test results provides a good method of identifying trends and anomalous results.

181

9.4 PRODUCT LEGALITY

The company shall have processes in place to ensure that the food products traded comply with the legal requirements in the country of sale where known.

Interpretation

The company needs to maintain awareness of, and ensure compliance with, relevant legal requirements for its products in the countries that the products are sold in. These may be associated with composition, labelling or how the products are sold.

CLAUSE	REQUIREMENTS
9.4.1	The company shall have documented processes to verify the legality of products which are traded. These processes shall include as appropriate:
	 labelling information compliance with relevant legal compositional requirements compliance with quantity or volume requirements.
	Where such responsibilities are undertaken by the customer, this shall be clearly stated in contracts.
Interpretation	Legal compliance Products traded must meet all of the legal requirements for the intended country of use. The site must therefore have processes to ensure it remains up to date with requirements such as labelling in that country and that these requirements are met and fulfilled.
	At a minimum the Standard requires labelling, composition, and quantity or volume requirements as applicable depending on the product to be considered.
	Where labelling is not controlled by the company but is the responsibility of the customer, this shall be clearly stated in contracts. Good practice is to ensure that all the relevant information is transferred to the customer and that any changes are communicated in a timely manner.

9.5 TRACEABILITY

The company shall be able to trace all product lots back to the last manufacturer and forward to the customer of the company.

Interpretation

In keeping with the traceability requirements for manufactured and processed products, sites that trade food products are required to maintain traceability, allowing food businesses and authorities to withdraw or recall products that have been identified as unsafe. The system must ensure that products supplied to customers are adequately labelled or identified to facilitate traceability. Traceability details need to be retained in a format that allows access in a timely manner.

CLAUS	E	REQUIREMENTS
9.5.1		The site shall maintain a traceability system for all batches of product which identify the last manufacturer or, in the case of primary agricultural products, the packer or place of last significant change to the product. Records shall also be maintained to identify the recipient of each batch of product from the company.
Interpre	tation	Identification of product Products may be identified by physical labelling or through the use of computerised bar-coding systems. The level of traceability must be able to identify the supplier of the product and to whom it is supplied (i.e. one step forward and one step back). This will enable the product to be identified if a particular batch needs to be recalled.
		Consider how the traceability system operates in practice (with the effective physical identification of products). For example, if batches or lots of product are broken down into smaller consignments for individual customers, is all of the necessary information available to the customer (i.e. was there any additional information on the original outer packaging that the customer would need to ensure traceability) and can the site confidently identify all of these individual customers?

CLAUSE	REQUIREMENTS
	Strict controls on identification, traceability and segregation are also required to preserve the integrity of any claims made, such as organic status. Where logos are used that make specific claims about production systems (e.g. farm assurance), full traceability and validations must be demonstrated (see also section 5.4).
9.5.2	The company shall test the traceability system at least annually to ensure that traceability can be determined back to the last manufacturer and forward to the recipient of the product from the company. This shall include identification of the movement of the product through the chain from the manufacturer to receipt by the company (e.g. each movement and intermediate place of storage).
Interpretation	Tests of the traceability system The site's traceability system for traded products must be tested at least annually. Traceability testing may be completed as part of a real product recall or withdrawal scenario if one has occurred, since the objective is to test the system and identify areas for improvement, rather than supply records of a 'test' for its own sake.
	The system must provide traceability 'forwards' and 'backwards'; therefore, the system should be tested in both directions. For example, a product could be selected and traced forwards to show to whom it was dispatched.
	Further information on the content of the BRC Global Standard audit, including the vertical audit, can be obtained from the BRC Global Standard guide to auditing techniques. The guide may be purchased from the BRC Global Standards bookshop (www.brcbookshop.com) or viewed online at BRC Participate (www.brcparticipate.com).
9.5.3	The traceability test shall include the reconciliation of quantities of product received by the company for the chosen batch or product lot. Traceability should be achievable within 4 hours (1 day when information is required from external parties).
Interpretation	Traceability results The test of traceability should be timed and full traceability would be expected to be achieved within 4 hours, unless information is required from external parties, such as suppliers. This is to reflect the need for rapid traceability in the event of a recall. Where traceability takes longer than 4 hours, review the areas where the retrieval of information is slow in order to identify improvements.
	The tests must also include a reconciliation of quantities (sometimes reference to as a quantity check or mass balance exercise). The objective is to be able to account for the usage of a full batch of product. This helps to ensure that the traceability systems are capable of operating effectively should a product recall be required.
	The reconciliation exercise is usually undertaken as follows:
	 Select a batch code of a particular specific product. Identify the quantity of product received under that batch code. Identify the customers purchasing that product and the amounts each received of the specific batch. Calculate the quantity of any unused part of the batch in the warehouse. Reconcile the quantity received against the amounts sold plus any residual unused stock.

^{*} Proceed to the next identified hazard in the described process.

Example of a decision tree to identify critical control points (CCPs)

^{**} Acceptable and unacceptable levels need to be defined within the overall objectives in identifying the CCPs of the HACCP plan.

APPENDIX 2 GLOSSARY

Accreditation	The procedure by which an authoritative body gives formal recognition of the competence of a certification body to provide certification services against a specified standard.
Adulterant	An undeclared material added into a food item or raw material for economic gain.
Adulteration	The addition of an undeclared material into a food item or raw material for economic gain.
Agent	A company that facilitates trade between a site or company and their raw material or packaging suppliers or their customers through the provision of services, but does not at any point own or take title to the goods.
Allergen	A known component of food which causes physiological reactions due to an immunological response (e.g. nuts and others identified in legislation relevant to the country of production or sale).
Ambient high care	An ambient area designed to a high standard where practices relating to personnel, ingredients, equipment, packaging and environment aim to minimise potential product contamination by pathogenic micro-organisms.
Announced audit	An audit where the company agrees the scheduled audit day in advance with the certification body.
Annual	Within 12 months since the action was last conducted.
Assured status	Products produced in accordance with a recognised product certification scheme, the status of which needs to be preserved through the certified production facility (e.g. GlobalG.A.P.).
ATP bioluminescence techniques	A rapid test for cleanliness of surfaces based on ATP (adenosine triphosphate) – a substance used in energy transfer in cells and therefore present in biological material.
Audit	A systematic examination to measure compliance of practices with a predetermined system, and whether the system is implemented effectively and is suitable to achieve objectives, carried out by certified bodies.
Auditor	A person possessing the appropriate competence and skills to carry out an audit.
Authenticity/authentic product	Food authenticity is ensuring that food or raw materials purchased and offered for sale, are of the nature, substance and quality expected.
Batch	The quantity of material prepared or required for one production operation.
Brand owner	The owner of a brand logo or name who places the said logo or name onto retail products.
Branded product	Products bearing the logo, copyright or address of a company that is not a retailer.
Broker	A company which purchases or 'takes title to' products for resale to businesses (e.g. manufacturers, retailers or food service companies) but not to the ultimate consumer.
Calibration	A set of operations that establish, under specified conditions, the relationship between values of quantities indicated by a measuring instrument or measuring system, or values represented by a material measure or reference material, and the corresponding values realised by standards.
Certificate suspension	Revocation of certification for a given period, pending remedial action on the part of the company.
Certificate withdrawal	Where certification is revoked. Certification may only be regained following successful completion of the full audit process.

Certification	The procedure by which an accredited certification body, based on an audit and assessment of a company's competence, provides written assurance that a company conforms to a standard's requirements.
Certification body	Provider of certification services, accredited to do so by an authoritative body and registered with BRC Global Standards.
Clause	A specific requirement or statement of intent that a site must comply with in order to achieve certification.
Cleaning in place (CIP)	The process of cleaning and sanitising food-processing equipment in its assembled position without the need for dismantling and cleaning the individual parts.
Codex Alimentarius Commission	A body responsible for establishing internationally recognised standards, codes of practice and guidelines, of which HACCP (hazard analysis and critical control points) is one standard.
Company	The entity with legal ownership of the site which is being audited against a BRC Global Standard.
Competence	Demonstrable ability to apply skill, knowledge and understanding of a task or subject to achieve intended results.
Compliance	Meeting the regulatory or customer requirements concerning product safety, legality and quality.
Consumer	The end-user of the finished product, commodity or service.
Contamination	Introduction or occurrence of an unwanted organism, taint or substance to packaging, food, raw material or the food environment. Contamination includes physical, chemical, radiological, biological and allergen contamination.
Contract packer	A company that packages the final product into consumer packaging.
Contractor or supplier	A person or organisation providing services or materials.
Control	To manage the conditions of an operation to maintain compliance with established criteria, and/or the state wherein correct procedures are being followed and criteria are being met.
Control measure	Any action or activity that can be used to prevent or eliminate a product safety hazard or reduce it to an acceptable level.
Controlled document	A document which is identifiable and for which revisions and removal from use can be tracked. The document is issued to specified individuals and their receipt of the document is recorded.
Cook	A thermal process designed to heat a food item to a minimum of 70°C for 2 minutes or equivalent (see Appendix 3 of the Standard). Alternative cooking processes may be accepted or required where these meet recognised national guidelines and are validated by scientific data.
Correction	Action to eliminate the cause of a detected non-conformity.
Critical control point (CCP)	A step at which control can be applied and is essential to prevent or eliminate a food or product safety hazard or reduce it to an acceptable level.
Cross-contamination/ cross-contact	The transfer of any material from one surface or food to another.
Cross-docking	Material is unloaded at distribution premises, and handled, but not formally put away into storage. This may be a staging area where inbound materials are sorted, consolidated and temporarily stored until the outbound shipment is complete and ready to ship.
Customer	A business or person to whom a service or product has been provided, either as a finished product or as a component part of the finished product.
Customer focus	A structured approach to determining and addressing the needs of an organisation to which the company supplies products and which may be measured by the use of performance indicators.
Despatch/dispatch	The point at which the product leaves the factory site or is no longer the responsibility of the company.
Distribution	The transportation of goods within any container (goods on the move) by road, rail, air or ship.
End-consumer	The ultimate consumer of a foodstuff, who will not use the food as part of any food business operation or activity.

Enclosed product area	An area of the factory where all products are fully enclosed and therefore not vulnerable to environmental contamination.
Flow diagram	A systematic representation of the sequence of steps or operations used in the production or manufacture of a particular food item.
Food defence	Procedures adopted to ensure the safety of raw materials and products from malicious contamination or theft.
Food fraud	Fraudulent and intentional substitution, dilution or addition to a product or raw material, or misrepresentation of the product or material, for the purpose of financial gain, by increasing the apparent value of the product or reducing the cost of its production.
Food handler	Anyone who handles or prepares food, whether open (unwrapped) or packaged.
Food integrity	Products that are of the nature, substance and quality expected (e.g. not substituted, diluted, adulterated or misrepresented).
Food raw materials	Food ingredients, additives and processing aids used in the manufacture of a product.
Food safety	Assurance that food will not cause harm to the consumer when it is prepared and/or eaten according to its intended use.
Food safety culture	The attitudes, values and/or beliefs which are prevalent at the site, relating to the importance of product safety and the confidence in the product safety systems, processes and procedures used by the site.
Food security	Procedures adopted to ensure the continued availability of raw materials and products.
Fundamental requirement	A requirement of the Standard that relates to a system which must be well established, continuously maintained and monitored by the company as absence or poor adherence to the system will have serious repercussions on the integrity or safety of the product supplied.
Genetically modified organism (GMO)	An organism whose genetic material has been altered by the techniques of genetic modification so that its DNA contains genes not normally found there.
Global Food Safety Initiative (GFSI)	Managed by the Consumer Goods Forum, a project to harmonise and benchmark international food safety standards (www.mygfsi.com).
Good hygiene practice	The combination of process, personnel and/or service control procedures intended to ensure that products and/or services consistently achieve appropriate levels of hygiene.
Good manufacturing practice (GMP)	Implemented procedures and practices undertaken using best-practice principles.
Hazard	An agent of any type with the potential to cause harm (usually biological, chemical, physical or radiological).
Hazard Analysis and Critical Control Point (HACCP)	A system that identifies, evaluates and controls hazards which are significant for food safety.
High-care area	An area designed to a high standard where practices relating to personnel, ingredients, equipment, packaging and environment aim to minimise product contamination by pathogenic micro-organisms.
High-care product	A product that requires chilling or freezing during storage, is vulnerable to the growth of pathogens, has received a process to reduce the microbiological contamination to safe levels (typically 1–2 log reduction) and is ready to eat or heat.
High-risk area	A physically segregated area, designed to a high standard of hygiene, where practices relating to personnel, ingredients, equipment, packaging and environment aim to prevent product contamination by pathogenic micro-organisms.
High-risk product	A chilled or frozen ready-to-eat/ready-to-heat product or food where there is a high risk of growth of pathogenic micro-organisms.
Identity preserved	A product which has a defined origin or purity characteristic which needs to be retained throughout the food chain (e.g. through traceability and protection from contamination).

Importer	A company facilitating the movement of products across an international border. Usually the first recipient of the products in that country.
Incident	An event that has occurred that may result in the production or supply of unsafe, illegal or non-conforming products.
Initial audit	The audit for certification to a BRC Global Standard at a company/site which is not in possession of a valid certificate. This may be the first audit at a site or a subsequent audit of a site whose certification has lapsed.
Inspection	Targeted verification (often a visual check against a 'tick list' for fabrication, environment and equipment) to ensure operation to safe expected levels.
Integrity	See food integrity.
Internal audit	General process of audit, for all the activity of the company. Conducted by or on behalf of the company for internal purposes.
Job description	A list of the responsibilities for a given position at a company.
Key staff	Those staff whose activities affect the safety, legality, integrity and quality of the finished product.
Legality	In compliance with the law in the place of production and in the countries where the product(s) is/are intended to be sold.
Lot	See batch.
Low-risk area	An area where the processing or handling of foods presents minimum risk of product contamination or growth of micro-organisms, or where the subsequent processing or preparation of the product by the consumer will ensure product safety.
Malicious contamination	Deliberate contamination of a product or raw material with the intention to cause harm to the consumer or damage to the company or brand owner.
Manufacturer	A company that produces product from raw materials and/or components and packs the product into retail units or supplies product in bulk to a packing company that packs the product into retail units. A packer that packs product into retail units from bulk-supplied material can also be classed as a manufacturer.
May	Indicates a requirement or text which provides guidance but is not mandatory for compliance with the Standard.
Mitigation strategies	Controls to remove, or reduce to an acceptable level, an identified risk, vulnerability or threat. It is often used in food defence where controls are needed to prevent potential threats from occurring.
Monitoring	A planned sequence of observations or measurements of defined control parameters to assess whether predefined limits are being met.
Non-conformity	The non-fulfilment of a specified product safety, legal or quality requirement or a specified system requirement.
Open product area	An area in which product is open to the environment (i.e. not fully enclosed in packaging or within equipment/pipes).
Outer packaging	Packaging which is visible when the product is released from the site. For example, a cardboard box could be considered outer packaging even if wrapped in clear film.
Outsourced processing (subcontracted processing)	Outsourced processing is where an intermediate production process or step in the manufacture of a product is completed at another company or site.
Ownership (change of company ownership)	A change of ownership occurs when the title is transferred from one individual or entity to another and results in a change of control of the organisation.
Performance indicators	Summaries of quantified data that provide information on the level of compliance against agreed targets (e.g. customer complaints, product incidents, laboratory data).
Positive release	Ensuring a product or material is of an acceptable standard prior to release for use.
Potable water	Water that is safe to drink, free from pollutants and harmful organisms, and conforms to local legal requirements.

Premises	A physical building or place owned by the company and audited as part of a site.
Pre-packaged products	Products in their final packaging that is designed for sale to the consumer.
Prepared primary product	A food product which has undergone a washing, trimming, size-grading or quality-grading process and is pre-packed.
Prerequisite	The basic environmental and operational conditions in a food business that are necessary for the production of safe food. These control generic hazards covering good manufacturing and hygiene practices, and shall be considered within the HACCP study.
Preventive action	Action to eliminate the fundamental, underlying cause (root cause) of a detected non-conformity and prevent recurrence.
Primary packaging	The packaging that constitutes the unit of sale to the consumer or customer (e.g. bottle, closure and label of a retail pack or a raw material bulk container).
Procedure	Agreed method of carrying out an activity or process which is implemented and documented in the form of detailed instructions or process description (e.g. a flowchart).
Processed food	A food product which has undergone any of the following processes: aseptic filling, baking, battering, blending, bottling, breading, brewing, canning, coating, cooking, curing, cutting, dicing, distillation, drying, extrusion, fermentation, freeze drying, freezing, frying, hot filling, irradiation, microfiltration, microwaving, milling, mixing, being packed in modified atmosphere, being packed in vacuum packing, pasteurisation, pickling, roasting, slicing, smoking, steaming or sterilisation.
Processing aid	Any substance not consumed as a food by itself, intentionally used in the processing of raw materials, foods or their ingredients to fulfil a certain technological purpose during treatment or processing, and which may result in the unintentional but technically unavoidable presence of the residues of the substance or its derivatives in the final product – provided that these residues do not present any health risk and do not have any technological effect on the finished product.
Product recall	Any measures aimed at achieving the return of an unfit product from customers and final consumers.
Product withdrawal	Any measures aimed at achieving the return of out-of-specification or unfit products from business customers, but not from final consumers.
Protective clothing	Clothing designed to protect the product from potential contamination by the wearer.
Provenance	The origin or the source of food or raw materials.
Quality	Meeting the customer's specification and expectation.
Quantity check/mass balance	A reconciliation of the amount of incoming raw material against the amount used in the resulting finished products, which also takes into account process waste and rework.
Quantity control	A check on the amount of product in the pack. May be related to weight, volume, number of pieces, size etc.
Quarantine	The status given to any material or product set aside while awaiting confirmation of its suitability for its intended use or sale.
Raw material	Any base material or semi-finished material used by the organisation for the manufacture of a product. Raw materials include food ingredients, packaging materials, additives, processing aids etc.
Ready-to-cook food	Food designed by the manufacturer to require cooking or other processing to effectively eliminate, or reduce to an acceptable level, micro-organisms of concern.
Ready-to-eat food	Food intended by the manufacturer for direct human consumption without the need for a full cook.
Ready-to-heat food	Food designed by the manufacturer to be suitable for direct human consumption without the need for cooking. The heating of the product is intended to make the product more palatable.
Recognised laboratory accreditation	Laboratory accreditation schemes that have gained national and international acceptance, have been awarded by a competent body, and are recognised by government bodies or users of the Standard (e.g. ISO/IEC 17025 or equivalents).
Reference sample	Agreed product or components for referral by the manufacturer for production.
Requirement	Those statements comprising a clause with which compliance will allow sites to be certificated.
	A trademark, logo, copyright or address of a retailer.

Retailer	A business selling products to the public by retail.
Retailer-branded products	Products bearing a retailer's logo, copyright, address or ingredients used to manufacture within a retailer's premises. These are products that are legally regarded as the responsibility of the retailer.
Retained production sample	Representative product or components taken from a production run and securely held for future reference.
Risk	The likelihood of occurrence of harm from a hazard.
Risk analysis	A process consisting of three components: risk assessment, risk management and risk communication.
Risk assessment	The identification, evaluation and estimation of the levels of risk involved in a process to determine an appropriate control process.
Root cause(s)	The underlying cause(s) of a problem, which, if adequately addressed, will prevent a recurrence of that problem.
Sampling plan	A documented plan defining the number of samples to be selected, the acceptance or rejection criteria and the statistical confidence of the result.
Satellite depot	A warehouse/distribution site receiving products only from another site within the same company.
Schedule	A tabulated statement giving details of actions and/or timings.
Seasonal production site	A site that is opened specifically to harvest and process a product for the duration of the short term of that harvest (typically 12 weeks or less) during a 12-month cycle.
Secondary packaging	Packaging that is used to collate and transport sales units to the retail environment (e.g. corrugated case).
Senior management	Those with strategic/high-level operational responsibility for the company and the capability to authorise the financial or human resources necessary for the implementation of the Standard.
Shall	Signifies a requirement to comply with the contents of the clause.
Should	Signifies that compliance with the contents of the clause or requirement is expected or desired.
Site	A unit of a company; the entity which is audited and which is the subject of the audit report and certificate.
Specification	An explicit or detailed description of a material, product or service.
Specifier	A company or person requesting the product or service.
Standard, the	The Global Standard for Food Safety Issue 8.
Supplier	The person, firm, company or other entity to which a site's purchase order to supply is addressed.
Suspension	Where certification is revoked for a given period, pending remedial action on the part of the company.
Threat assessment	A risk assessment designed to examine site processes for potential product security and food defence issues.
Traceability	Ability to trace and follow raw materials, components and products, through all stages of receipt, production, processing and distribution both forwards and backwards.
Traded goods/products	Goods that are not manufactured or further processed on site but bought from an outside supplier, stored at the site and sold on.
Trend	An identified pattern of results.
Unannounced audit	An audit undertaken on a date unknown to the company in advance.
User	The person or organisation who requests information from the company regarding certification.
Utilities	Commodities or services, such as electricity or water, that are provided by a public body.
Validation	Obtaining evidence through the provision of objective evidence that a control or measure, if properly implemented, is capable of delivering the specified outcome.
Vehicle	Any device used for the conveyance of product that is capable of being moved upon highways, waterways or airways. Vehicles can be motorised (e.g. a lorry) or non-motorised (e.g. container or rail truck).

The application of methods, procedures, tests and other evaluations, in addition to monitoring,
to determine whether a control or measure is or has been operating as intended.
A risk assessment designed to examine processes and supply chains for potential food fraud. BRC Global Standards has developed a guideline to assist sites with vulnerability assessments.
In relation to a requirement of the Standard, the company will assess the need for the requirement and, where applicable, put in place systems, processes, procedures or equipment to meet the requirement. The company shall be mindful of legal requirements, best-practice standards, good manufacturing practice and industry guidance, and any other information relating to the manufacture of safe and legal product.
Partially manufactured products, intermediates or materials waiting for completion of the manufacturing process.
Company-issued or authorised clothing designed to protect the product from potential contamination by the wearer.

APPENDIX 3 SOURCES OF FURTHER INFORMATION

BRC GLOBAL STANDARDS

A series of globally recognised certification standards for manufacturers and for storage and distribution companies.

www.brcglobalstandards.com

BRC GUIDELINES

BRC Global Standards publishes a series of best-practice guidelines on topics including complaint handling, pest control, internal auditing, product recall, traceability and foreign-body detection. These may be purchased from the BRC Global Standards bookshop **www.brcbookshop.com** or viewed online at BRC Participate **www.brcparticipate.com**.

BRC ACADEMY

The BRC Academy provides businesses and individuals with Global Standards training and personal development programmes.

www.brctrainingacademy.com

CODEX ALIMENTARIUS

The Codex Alimentarius Commission was created in 1963 by FAO and WHO to develop food standards, guidelines and related texts such as codes of practice under the Joint FAO/WHO Food Standards Programme.

The downloadable Food Hygiene – Basic Texts 2003 includes HACCP steps:

www.fao.org/docrep/012/a1552e/a1552e00.htm

Other Codex standards that can be downloaded are available here:

www.codexalimentarius.org/standards/list-of-standards

FOOD AND DRUG ADMINISTRATION (FDA) OF THE UNITED STATES 'BAD BUG BOOK'

Examples of microbiological sources.

www.fda.gov/food/foodborneillnesscontaminants/causesofillnessbadbugbook/default.htm

RASFF

The Rapid Alert System for Food and Feed (RASFF), established in 1979, enables the rapid exchange of information whenever a risk to food or feed safety is identified. Members comprise 27 member states, the European Commission, the European Food Safety Authority, Iceland, Liechtenstein and Norway. This is part of the Europa website.

http://ec.europa.eu/food/food/rapidalert/index_en.htm
